Abstract

A Cephoid is a Minkowski sum of finitely many prisms in $\mathbb{R}^n$. We discuss the concept of duality for Cephoids. Also, we show that the reference number uniquely defines a face. Based on these results, we exhibit two graphs on the outer surface of a cephoid. The first one corresponds to a maximal face and its reference system. The second graph describes the generalized tentacles.
1 Introduction

A cepheid is a sum of prisms. Given a vector \( \mathbf{a} = (a_1, \ldots, a_n) > 0 \in \mathbb{R}^n \), we write \( \mathbf{e}^i \) for the \( i^{th} \) unit vector and \( \mathbf{a}^i := a_i \mathbf{e}^i \) \((i \in I := \{1, \ldots, n\})\). We call \( \Pi^\mathbf{a} := \text{convH} \{\{0, \mathbf{a}^1, \ldots, \mathbf{a}^n\}\} \) a prism. The (outward) surface is the simplex \( \Delta^\mathbf{a} := \text{convH} \{\{\mathbf{a}^1, \ldots, \mathbf{a}^n\}\} \); its subsimplices are denoted by \( \Delta_j^\mathbf{a} := \text{convH}((\mathbf{a}^{(i)})_{i \in J}) \) for \( \emptyset \neq J \subseteq I \).

Thus, if \( \mathbf{a}^\ast = (\mathbf{a}^{(k)})_{k=1}^K = (\mathbf{a}^{(k)})_{k \in K} \) is a family of positive vectors, then the algebraic or Minkowski sum

\[
\Pi = \Pi^\mathbf{a}^\ast := \sum_{k=1}^K \Pi^{(k)} =: \sum_{k \in K} \Pi^{(k)}
\]

\( \Pi \) is called a cepheid. Cepheids have been introduced in [3], see also [5],[4]. Throughout this paper we assume that a cepheid is nondegenerate, see [3] for the details.

The outer surface (“Pareto surface”, “cephoidal surface”) of a cepheid \( \Pi \) is denoted by \( \partial \Pi \). In order to describe the maximal faces of \( \partial \Pi \), it is appropriate to recall the “Coincidence Theorem” ([3]). It states the following. Given some maximal face \( \mathbf{F} \) of \( \partial \Pi \), one can construct a simplex as the convex hull (or “maximum”) of suitably “adjusted” (i.e. by taking positive multiples) subsimplices \( c_k^\ast \Delta_j^{(k)} \) written

\[
\bigvee_{k \in K} c_k^\ast \Delta_j^{(k)}.
\]

The sets \( J^{(k)} \) are called the reference sets, the collection \( J = \left(J^{(k)}\right)_{k \in K} \) is the reference system of \( \mathbf{F} \). The reference system defines \( \mathbf{F} \) uniquely, the adjustment coefficients \( c_k^\ast \) are determined uniquely up to a positive multiple. The set

\[
\mathbf{L} := \{l \in I \mid l \text{ appears in at least two sets } J^{(k)}\}
\]

is called the adjustment set. It serves to determine the normal of \( \mathbf{F} \) as follows. We write \( \mathbf{L}^{(k)} := \mathbf{L} \cap J^{(k)} \) and

\[
\mathbf{L} := \{(k,l) \mid l \in \mathbf{L}, J^{(k)} \ni l\} = \{(k,l) \mid l \in \mathbf{L}^{(k)}\}
\]

and obtain the linear adjustment system which is the homogeneous linear system of equations in variables \( (c_k, \lambda_l) \), \((k,l) \in \mathbf{L})\), given by

\[
c_k a^{(k)}_l = \lambda_l \quad ((k,l) \in \mathbf{L}).
\]

As has been shown in [3], this system (depending on \( \mathbf{F} \)) has a unique solution (up to a positive constant) \((c_\ast^\ast, \lambda_\ast^\ast)\), the first ingredients of which yield the adjustment coefficients. Moreover, the normal \( \mathbf{n}^\ast \) of \( \mathbf{F} \) is obtained by computing

\[
a_i^\ast := \max_{k \in K} c_k^\ast a^{(k)}_i \quad (i \in I)
\]
\[ n^* = \left( \frac{1}{a_1^*}, \ldots, \frac{1}{a_n^*} \right). \]

Finally, note that the linear functional \( x \mapsto n^* x \) attains its maximum relative to \( \Pi^{(k)} = \Pi^{a(k)} \) exactly on \( \Delta_{J(\alpha)}^{(k)} \). “Adjustment” means that the maximal value of this functional relative to \( c_k^* \Pi^{(k)} \) (which is attained exactly on \( c_k^* \Delta_{J(\alpha)}^{(k)} \))
equals some common value \( t^* \) for all \( k \in K \) – which is why \( n^* \) is indeed the normal to
\[
\bigvee_{k \in K} c_k^* \Delta_{J(\alpha)}^{(k)}.
\]

Within this paper we start out by introducing a notion of duality of cephoids. Based on this we exhibit the bijection between reference vectors and maximal faces. Then we continue to explore the structure of faces as well the one of cephoidal surfaces.
2 Duality

As we have seen, a cephoid is provided by a family of positive vectors or, equivalently, by a positive matrix, the rows of which represent the various prisms. The dual cephoid, very simply, is provided by the transposed matrix. More precisely, we supply the following definition.

Definition 2.1. Let \( a^* = \left( a_{k \in K}^{(k)} \right) \) be a family of positive vectors and \( \Pi = \Pi a^* = \sum_{k \in K} \Pi a^{(k)} \) be the cephoid generated. Put \( \bar{a}_k^{(i)} := a_i^{(k)} (i \in I, k \in K) \). We call the family
\[
(\bar{a}^{(i)})_{i \in I}
\]
the dual family and the cephoid
\[
\bar{\Pi} = \Pi a^* = \sum_{i \in I} \Pi \bar{a}^{(i)}
\]
the dual cephoid.

More detailed, \((\Pi, \bar{\Pi})\) constitutes a dual pair. Yet, it is convenient to speak of the “primal” and “dual” cephoid despite the fact that each is “the dual” of the other one. If the “primal” family \( a^* \) is regarded as a matrix, then the “dual” family is represented by the transposed matrix \((\bar{a}_k^{(i)})_{i \in I, k \in K}\). Throughout this presentation we assume nondegeneracy for the primal and dual cephoid simultaneously.

Definition 2.2. Let \( F \) be a maximal face of \( \Pi \) and let \( \mathcal{J} = \left( J^{(k)} \right)_{k \in K} \) be the reference system. Define, for \( i \in I \)
\[
J^{(i)} := \{ k \in K \mid i \in J^{(k)} \}. 
\]
Then we call
\[
\mathcal{J} = \left( J^{(i)} \right)_{i \in I}
\]
the dual reference system.

Clearly we have, for any \( k \in K \)
\[
J^{(k)} = \{ i \in I \mid k \in J^{(i)} \},
\]
so \((\mathcal{J}, \mathcal{J})\) again constitute a dual pair. In fact, we may introduce the set
\[
\mathcal{J} := \{ (k, i) \mid i \in J^{(k)} \} = \{ (i, k) \mid k \in J^{(i)} \}
\]
which yields both families simultaneously as cuts in coordinate directions. As a consequence, we have
\[
n + K - 1 = \sum_{k \in K} |J^{(k)}| = |\mathcal{J}| = \sum_{i \in I} |J^{(i)}|.
\]
Definition 2.3.
\[ L := \left\{ k \in K \mid k \text{ is in at least two different } J^{(i)} \right\} \]
\[ = \left\{ k \in K \mid J^{(k)} \text{ contains at least two different indices } i \right\} \]
\[ = \left\{ k \in K \mid |J^{(k)}| \geq 2 \right\} \]

is the dual adjustment set. The analogous property of the primal adjustment set reads now
\[ L := \left\{ i \in I \mid i \text{ is in at least two of the } J^{(k)} \right\} \]
\[ = \left\{ i \in I \mid |J^{(i)}| \geq 2 \right\} . \]

Recalling the notation
\[ \mathbb{L} := \left\{ (k, l) \mid l \in L, J^{(k)} \ni l \right\} = \left\{ (k, l) \mid l \in L^{(k)} \right\} , \]
we obtain the dual version
\[ \mathbb{L} := \left\{ (i, s) \mid s \in \mathbb{L}, J^{(i)} \ni s \right\} = \left\{ (i, s) \mid s \in L^{(i)} \right\} \]
\[ = \left\{ (i, s) \mid i \in J^{(s)}, |J^{(s)}| \geq 2 \right\} . \]

Now we are in the position to formulate

**Theorem 2.4.** Let \( \alpha^* \) and its dual be in general position. Let \( F \) be a maximal face of \( \Pi \) with reference system \( \mathcal{J} \). Let
\[ (c^*, \lambda^*) = (c^*_k, \lambda^*_i)_{(k, l) \in \mathbb{L}} \]
be a solution of the linear adjustment system corresponding to \( F \). Then
\[ \bar{F} := \sum_{i \in I} \Delta^{(i)}_{J^{(i)}} \]
is a maximal face of \( \bar{\Pi} \) with adjustment set \( \bar{L} \) and normal \( c^* \).

**Proof:**

Let \( n^* \) denote the normal of \( F \); then we know that the function \( x \mapsto n^* x \) attains its maximal value – say \( t_k \) – relative to the simplex \( \Delta^{(k)} \) exactly on the subsimplex \( \Delta^{(k)}_{J^{(k)}} \). Moreover, the joint maximal value \( t^* \) is attained on every \( c^*_k \Delta^{(k)}_{J^{(k)}} \) (with a suitable choice of \( c^*_k \), say \( c^*_k = \frac{t_k}{k} \)).

Consequently, we have
\[ n^* c^*_k a^{(k)i} \]
\[ \begin{cases} = t^* & ((k, i) \in \mathcal{J}) \\ < t^* & ((k, i) \notin \mathcal{J}) \end{cases} \]
which can as well be written
\[(2.13) \quad n_i^* a_i^{(k)} c_k^* \begin{cases} \ = \ t^* \ (k, i) \in \mathcal{J} \\ \ < \ t^* \ (k, i) \notin \mathcal{J} \end{cases} \]

Equivalently we have
\[c_k^* a_i^{(j)} n_i^* \begin{cases} \ = \ t^* \ (k, i) \in \mathcal{J} \\ \ < \ t^* \ (k, i) \notin \mathcal{J} \end{cases} \]

which is also
\[(2.14) \quad c_k^* n_i^* a_i^{(j)k} \begin{cases} \ = \ t^* \ (k \in \mathcal{J}(i)) \\ \ < \ t^* \ (k \notin \mathcal{J}(i)) \end{cases} \]

Now, equation (2.14) shows that, for each \(i \in I\), the function \(y \mapsto c^* y\) attains its maximal value \(t^*\) relative to \(n_i^* \hat{\Sigma}^{(i)}\) exactly on \(n_i^* \hat{\Sigma}^{(i)}\). Thus, \(c^*\) is normal to
\[(2.15) \quad \hat{\Sigma} := \bigvee_{i \in I} n_i^* \hat{\Sigma}^{(i)} .\]

2ndSTEP: Since \(\mathcal{J}^{(k)} \neq \emptyset\) for all \(k \in K\), there is, for any \(k \in K\), some \(i \in I\) such that \(i \in \mathcal{J}^{(k)}\) holds true. Therefore
\[\bigcup_{i \in I} \mathcal{J}(i) = \bigcup_{i \in I} \left\{ k \in K \mid i \in \mathcal{J}^{(k)} \right\} = K .\]

Now, as \(\hat{\Sigma}\) is spanned by \(n_i^* \hat{\Sigma}^{(i)}\), we conclude that the dimension is \(\dim \hat{\Sigma} = K - 1\), that is, the simplex \(\hat{\Sigma}\) has maximal dimension. Moreover, we have for the dimension of the spanning subsimplices
\[(2.16) \quad \sum_{i \in I} \dim \hat{\Sigma}^{(i)} = \sum_{i \in I} (|\mathcal{J}(i)| - 1) = (\sum_{i \in I} \bar{r}_i) - n = (n + K - 1) - n = K - 1 ,\]

where the second equation follows from \(|I| = n\) and the third one from equations (2.7). Also, we use \(\bar{r}_i := |\mathcal{J}(i)|\).

3rdSTEP: The function \(y \mapsto c^* y\) takes its maximal value relative to \(\hat{\Sigma}^{(i)}\) exactly on \(\hat{\Sigma}^{(i)}\); this value is \(\frac{c_i}{n_i}\) for \(i \in I\). Therefore it is seen that
\[(2.17) \quad \hat{F} = \sum_{i \in I} \hat{\Sigma}^{(i)} .\]

as specified in (2.12) is a face of \(\hat{\Pi}\) with normal \(c^*\).

We show that \(|\mathcal{J}^{(i)} \cap \mathcal{J}^{(j)}| \leq 1\) for all \(i \neq j\). Assume that, on the contrary, we have \(r, s \in \mathcal{J}^{(i)} \cap \mathcal{J}^{(j)}\) for some \(r \neq s\). In view of (2.13) we obtain the following equations:
\[n_r^* a_r^{(1)} c_1^* = n_s^* a_s^{(1)} c_1^* \]
\[n_r^* a_r^{(2)} c_2^* = n_s^* a_s^{(2)} c_2^* \]
Dividing both equations we obtain
\[
\frac{d_{r}^{(1)} c_1^*}{a_r^{(2)} c_2^*} = \frac{d_{s}^{(1)} c_1^*}{a_s^{(2)} c_2^*},
\]
that is,
\[
\frac{d_{r}^{(1)}}{a_r^{(2)}} = \frac{d_{s}^{(1)}}{a_s^{(2)}},
\]
contradicting nondegeneracy.

Consequently, all subsimplices \( \sum_{j(i)} \) are located in pairwise orthogonal subspaces. This implies
\[
\text{dim} \left( \sum_{i \in I} \sum_{j(i)} \right) = \sum_{i \in I} \text{dim} \sum_{j(i)} = K - 1,
\]
meaning that \( F \) is indeed maximal.

q.e.d.

Remark 2.5. The set \( L \) is the adjustment set for \( F \). We write \( L := |L| \).
That is, whenever \( s \in L \), say \( s \in J^{(i')} \cap J^{(i'')} \) for suitable \( i', i'' \in I \) then the vertex
\[
n_{i'}^{*} a^{(i')} s = n_{i''}^{*} a^{(i'')} s
\]
is common to the subsimplices \( n_{i'}^{*} \tilde{a}^{(i')} \) and \( n_{i''}^{*} \tilde{a}^{(i'')} \). Now recall that, for \( i \in I \setminus L \), the set \( J^{(i)} \) consists of just one element. Therefore, using (2.7) and writing \( \bar{r}_i := |J^{(i)}| \), we obtain
\[
\sum_{i \in L} \bar{r}_i = \sum_{i \in I \setminus L} \bar{r}_i = \sum_{i \in I} \bar{r}_i - \sum_{i \in I, \bar{r}_i = 1} \bar{r}_i = (n + K - 1) - (n - L) = K + L - 1
\]
or
\[
\sum_{i \in L} |J^{(i)}| = K + L - 1 = \sum_{k \in K} |L^{(k)}|,
\]
the last equation is derived from [3], Section 3, (3.11).

The analogue equation connecting the primal reference sets with the dual adjustment sets in size is based in the definition \( \tilde{L}^{(i)} := L \cap J^{(i)} (i \in I) \) and reads
\[
\sum_{k \in \tilde{L}} |J^{(k)}| = n + \tilde{L} - 1 = \sum_{i \in L} \tilde{L}^{(i)}.
\]
Remark 2.6. Recall that the linear adjustment system with respect to the face $F$ is given by
\begin{equation}
(2.23) \quad c_k a_l^{(k)} = \lambda_l \quad ((k, l) \in \mathbb{L}).
\end{equation}
Clearly, the dual linear adjustment system is the linear system of equations in variables $(n_s, \mu_s)$
\begin{equation}
(2.24) \quad \bar{a}^{(s)}_i n_i = \mu_s \quad ((i, s) \in \mathbb{L}).
\end{equation}
As in the primal case, every solution $n^*$ induces the normal of the dual face. Indeed, define
\begin{equation}
(2.25) \quad \bar{a}^*_k := \max_{i \in I} n^* \bar{a}^{(s)}_k = \max_{i \in I} n^*_k \bar{a}^{(s)}_k,
\end{equation}
then the vector $\bar{a}^*$ defines the simplex $\hat{\Delta}$, i.e., $\Delta = \Delta \bar{a}^*$ and hence
\begin{equation}
(2.26) \quad c^*_k = \frac{1}{\bar{a}^*_k} \quad (k \in K)
\end{equation}
defines the normal $c^*$ to the dual face $\bar{F}$. This way we see that the adjustment coefficients of the primal face constitute the normal of the dual face and vice versa. In particular, the system (2.24) directly serves to compute the normal of the face. Using only primal terms, we write this system
\begin{equation}
(2.27) \quad a^{(s)}_i n_i = \mu_s \quad ((i, s) \in I \times K, i \in J^{(s)}, |J^{(s)}| \geq 2)
\end{equation}

Corollary 2.7. Let $(\Pi, \bar{\Pi})$ be a dual pair. Let $F$ and $\bar{F}$ be adjacent maximal faces of $\Pi$. Then the dual faces $\bar{F}$ and $\bar{F}$ are adjacent.

Proof: Let $J = \left( J^{(k)} \right)_{k \in K}$ and $\bar{J} = \left( J^{(k)} \right)_{k \in K}$ be the reference systems to $F$ and $\bar{F}$ respectively. By the Neighborhood Theorem there are indices $k_0, l_0 \in K$ as well as $p, q \in I$ such that $p \notin J^{(k_0)}, q \in J^{(k_0)}$
\begin{equation}
(2.28) \quad \bar{J}^{(k_0)} = J^{(k_0)} \cup \{p\}, \quad \bar{J}^{(l_0)} = J^{(l_0)} \setminus \{q\}
\end{equation}
while for all indices $k \in K, k \neq k_0, l_0$ the reference sets $J^{(k)}$ and $\bar{J}^{(k)}$ coincide. are equal. Inspection of Definition 2.2 shows that
\begin{equation}
(2.29) \quad \bar{J}^{(p)} = J^{(p)} \cup \{k_0\}, \quad \bar{J}^{(q)} = J^{(q)} \setminus \{l_0\}
\end{equation}
while for all $i \neq p, q$ the reference sets $J^{(i)}$ and $\bar{J}^{(i)}$ coincide. From this it follows that $\bar{F}$ and $\bar{F}$ are adjacent. q.e.d.

Note however that the complete p.o. structure of $\partial \Pi$ is not preserved during the transition to the dual. The following example enlightens vividly the relevant aspects.
Example 2.8. Consider in particular the case that $K = 2$, i.e., $K = \{1, 2\}$, thus we have $\Pi = \Pi^a + \Pi^b$. We know that the cepheidal surface $\partial \Pi$ is completely described by a permutation or ordering $\prec$ such that all maximal faces are of the shape

$$F^{\prec i_0} = \Delta^a_{\{i \leq i_0\}} + \Delta^b_{\{\| i \leq i_0 \}}.$$ 

The reference system for $F^{\prec i_0}$ is thus

$$\{ J^{(1)}, J^{(2)} \} \rightarrow \{ \{ i \leq i_0 \}, \{ i \leq i \} \}.$$ 

Consequently, we find for the corresponding dual reference system

$$J^{(i)} = \{ k \in K \mid i \in J^{(k)} \}$$

the following: whenever $i < i_0$, then obviously

$$J^{(i)} = \{ 1 \},$$

and whenever $i_0 < i$, then

$$J^{(i)} = \{ 2 \}$$

holds true. For $i = i_0$ we obtain

$$J^{(i)} = \{ 1, 2 \}$$

so that the dual face to $F^{\prec i_0}$ is

$$F^{\prec i_0} = \sum_{i < i_0} a^{(1)i} + \Delta^a_{\{1, 2\}} + \sum_{i_0 < i} a^{(2)i}.$$ 

Thus, the Pareto or cepheidal surface of $\tilde{\Pi}$ is a linear curve with line segments being the translates of the various $\Delta^a_{\{1, 2\}}$. If $i_0$ is the first w.r.t. $\prec$, then the face

$$F^{\prec i_0} = \Delta^a_{\{1, 2\}} + \sum_{i \neq i_0} a^{(2)i}.$$ 

is the “uppermost” line segment, i.e., the first in the ordering induced by the slope when we begin with the smallest slope (in absolute value). Thus, it is seen that $\prec$ represents as well the ordering of the line segments within the cepheidal surface of the dual cepheid.

In particular, consider Example 4.4. of [3] which treats a case with $n = 4$. A sketch of the canonical representation is provided by Figure 2.1. Assuming that the translate of $\Delta^a$ occupies the first vertex of the sum (i.e., $2e^i$), and the translate of $\Delta^b$ the second one, the left hand version of Figure 2.1 corresponds to the ordering $\prec = (2341)$. The 3-dimensional faces are given by

$$F^{\prec 2} = \Delta^a_2 + \Delta^b_{341},$$

$$F^{\prec 3} = \Delta^a_{23} + \Delta^b_{341},$$

$$F^{\prec 4} = \Delta^a_{234} + \Delta^b_{341},$$

$$F^{\prec 1} = \Delta^a_{2341} + \Delta^b_1.$$
Figure 2.1: The sum of two prisms for \( n = 4 \)

The ordering \(<\) represents the neighborhood structure of the four faces simultaneously indicating the unique extremal vector \( \mathbf{c}^i = \mathbf{a}^i + \mathbf{b}^i \) assigned to a face. If we start with \( \mathbf{F}^{<2} \) containing \( \mathbf{c}^2 \), then the unique neighbor is \( \mathbf{F}^{<3} \) containing \( \mathbf{c}^3 \) etc. Thus, while running through the extremals \( \mathbf{c}^i \) according to \(<\) one also passes from one face to its neighbor.

The same situation occurs with respect to the dual cephoid \( \mathbf{\Pi} \). The dual face to \( \mathbf{F}^{<2} \) i.e., generated by the reference system \( \mathbf{\delta} = \{\{2\}, \{2341\}\} \) is \( \mathbf{\bar{F}}^{<2} \) which is given by

\[
\mathbf{\bar{F}} = \{\{2\}, \{12\}, \{2\}, \{2\}\}
\]

i.e.,

\[
\mathbf{\bar{F}}^{<2} = \Delta_{\{2\}}^{(1)} + \Delta_{\{12\}}^{(2)} + \Delta_{\{2\}}^{(3)} + \Delta_{\{2\}}^{(4)}
\]

this is a translate of \( \Delta_{\{12\}}^{(2)} \) by means of \( \mathbf{a}^{(1)2} + \mathbf{a}^{(3)2} + \mathbf{a}^{(4)2} \). Similarly,

\[
\mathbf{\bar{F}}^{<3} = \Delta_{\{2\}}^{(1)} + \Delta_{\{1\}}^{(2)} + \Delta_{\{12\}}^{(3)} + \Delta_{\{12\}}^{(4)}
\]

is a translate of \( +\Delta_{\{12\}}^{(3)} \). The further two dual faces are.

\[
\mathbf{\bar{F}}^{<4} = \Delta_{\{2\}}^{(1)} + \Delta_{\{1\}}^{(2)} + \Delta_{\{1\}}^{(3)} + \Delta_{\{1\}}^{(4)}
\]

and

\[
\mathbf{\bar{F}}^{<1} = \Delta_{\{12\}}^{(1)} + \Delta_{\{1\}}^{(2)} + \Delta_{\{1\}}^{(3)} + \Delta_{\{1\}}^{(4)}
\]

The cephoidal surface \( \partial\mathbf{\Pi} \) is sketched together with its canonical representation in Figure 2.2. When we start in the uppermost face and run through the faces according to \(<\), then we pass all faces in downwards direction.

Example 2.9. Next we discuss an example with \( n = 4, K = 3 \) named “The Marriage of a Windmill and a Circle”. The canonical representation
is given by Figure 2.3. We use $a, b, c$ for the primal family assuming that $\Delta^{(a)}$ corresponds to “blue”, $\Delta^{(b)}$ corresponds to “red”, and $\Delta^{(c)}$ corresponds to “green”.

The maximal faces as indicated are defined by the following reference sets:

![Figure 2.2: The dual surface and its canonical representation](image)

![Figure 2.3: The Marriage of a windmill and a circle](image)
The dual cephoid is the sum of 4 prisms in 3 dimensions, we denote the dual family by $\bar{a}^{(1)}$. The canonical representation is given by the following sketch.

Figure 2.4: The Dual Marriage

The maximal faces are listed in the same order as its primal counterparts.
and indicated accordingly. We obtain the following list.

\[
\begin{array}{|c|c|c|c|c|}
\hline
\text{Name} & \mathcal{F}^{(1)} & \mathcal{F}^{(2)} & \mathcal{F}^{(3)} & \mathcal{F}^{(4)} \\
\hline
\Delta^{(a)} & \{13\} & \{12\} & \{1\} & \{1\} \\
\Gamma^{(a)}|c\rangle & \{3\} & \{123\} & \{1\} & \{1\} \\
\Gamma^{(a)}|b\rangle & \{13\} & \{2\} & \{12\} & \{1\} \\
\hline
\Delta^{(b)} & \{23\} & \{2\} & \{2\} & \{12\} \\
\Gamma^{(b)}|c\rangle & \{3\} & \{2\} & \{2\} & \{123\} \\
\Gamma^{(b)}|a\rangle & \{123\} & \{2\} & \{2\} & \{1\} \\
\hline
\Delta^{(c)} & \{3\} & \{3\} & \{123\} & \{3\} \\
\Gamma^{(c)}|b\rangle & \{3\} & \{23\} & \{12\} & \{3\} \\
\Gamma^{(c)}|a\rangle & \{3\} & \{23\} & \{1\} & \{13\} \\
\hline
\bar{B}^{(a)}|b\rangle|c\rangle & \{3\} & \{2\} & \{12\} & \{13\} \\
\hline
\end{array}
\]

(2.37)
3 The Reference Vector

Given a maximal face

\[ F = \sum_{k=1}^{K} \Delta_{J^{(k)}} \]

of a cephoid \( \Pi \), we write

\[ r_k := |J^{(k)}| \quad (k \in K) \]

and call \( r = (r_1, \ldots, r_K) \) the reference vector of \( F \). We are going to show that the reference vector uniquely defines the face. To this end, we list the main properties of such a vector.

**Definition 3.1.** Let \( n, K \in \mathbb{N} \). A vector \( r = (r_1, \ldots, r_K) \in \mathbb{N}_0^K \) is said to be a \((K, n)\)-reference code if

\[ 0 \leq r_k \leq n \quad (k \in K) \]

and

\[ \sum_{k=1}^{K} r_k \leq K + n - 1 \]

holds true. A reference code \( r \) is **maximal** if an equation prevails in (3.2).

**Theorem 3.2.** Let \( a^* = \{a^{(k)}\}_{k \in K} \) be a nondegenerate family of positive vectors in \( \mathbb{R}^n \). Then, for every maximal \((K, n)\)-reference code \( r \) there exists a unique maximal face \( F \) of \( \Pi = \sum_{k \in K} \Pi^{(k)} \) with reference system

\[ \{J^{(k)}\}_{k \in K} \]

with

\[ |J^{(k)}| = r_k \quad (k \in K) \],

i.e., \( r \) is the reference vector of \( F \).

**Proof:** 1\textsuperscript{st}STEP: For \( n = 2 \) the Theorem is obvious. For \( K = 2 \) the Theorem follows from Theorem 4.2 of [3], see also Remark 4.3. of [3]. Of course, the case \( K = 2 \) follows as well by duality as explained in the previous section.

Now we proceed by induction.

2\textsuperscript{nd}STEP:

First of all assume \( K \leq n - 1 \). Let \( F \) be a maximal face and let

\[ F = \sum_{k=1}^{K} \Delta_{J^{(k)}} \]
be the representation via the reference system. Also, let $L$ be the set of adjustment indices. As $L = |L| \leq n - 2$, there are at least two indices, say 1 and $n$, that do not belong to $L$. As a consequence $F|_{R_{l-1}}$ and $F|_{R_{l-n}}$ are maximal faces of the families $a^*|_{R_{l-1}}$ and $a^*|_{R_{l-n}}$ respectively. The reference codes are $(r_1, \ldots, r_k - 1, \ldots, r_K)$ and $(r_1, \ldots, r_l - 1, \ldots, r_K)$ with suitable $k, l \in K$. By induction, these reference codes uniquely determine the reference systems

$$\left\{ J^{(k)} \setminus \{1\} \right\}_{k \in K}, \quad \left\{ J^{(k)} \setminus \{n\} \right\}_{k \in K}$$

of two faces of the restrictions of $\Pi$ to $R^{I-1}$ and $R^{I-n}$ respectively. Hence the reference system

$$\left\{ J^{(k)} \right\}_{k \in K}$$

of $F$ is uniquely determined by $r$. This shows, that there is at most one face corresponding to a reference code, provided $K \leq n - 1$ holds true.

But for $K \geq n$ we know that every maximal face is the sum of at most $n - 1$ subfaces of the $\Delta^{(k)}$ plus a number of vertices from the remaining ones. In other words, every face is $r$-full for some $r \leq n - 1$ (see [3]) By the above argument, with respect to the $n - 1$ faces that yield reference sets of size at least 2, these reference sets are uniquely defined. The remaining vertices, however, are uniquely defined as well.

Thus, a reference code defines a face uniquely, if at all.

3rdSTEP:

On the other hand, given a family $a^*$ and the cephoid $\Pi$ generated, let $\mathfrak{F}(K, n)$ be the set of maximal faces of $\Pi$. Let $\Pi|_{I-n}$ be the cephoid generated by the family $a|_{R_{I-n}}$ of vectors projected onto $R_{I-n}$ and let $\mathfrak{F}(K, n-1)$ denote the family of its maximal faces.

Similarly, let $\Pi^{(-K)} = \sum_{K=1}^{K-1} \Pi^{(k)}$ be the sum of the first $K - 1$ prisms and let $\mathfrak{F}(K-1, n)$ denote the system of maximal faces of this cephoid. The induction hypothesis applies to both cephoids constructed.

Now, let $F \in \mathfrak{F}(K, n)$ and let $r$ be its reference vector. First of all, assume that $r_K = 1$ is the case, that is, $F$ consists of a face $F^{(-K)}$ of $\Pi^{(-K)}$ plus a vertex of $\Delta^{(K)}$. By induction, the face $F^{(-K)}$ is uniquely defined by $(r_1, \ldots, r_{K-1})$ and the remaining vertex of $\Delta^{(K)}$ is uniquely defined as well. On the other hand, every face $\Pi^{(-K)}$ together with a suitable and unique vertex of $\Delta^{(K)}$ yields a face in $\mathfrak{F}(K - 1, n)$. Thus, $\mathfrak{F}(K - 1, n)$ and the set

$$\left\{ F \in \mathfrak{F}(K, n) \right\} r_K = |J^{(K)}| = 1$$

are bijectively mapped into each other in a canonical way.

4thSTEP:

Next, let $F \in \mathfrak{F}(K, n)$ be such that $r_K = |J^{(K)}| \geq 2$ is true. By induction, there is a unique maximal face, say $F^* \in \mathfrak{F}(K, n - 1)$ of $\Pi|_{R_{I-n}}$ that corresponds to the reference vector $(r_1, \ldots, r_{K-1})$. By the first step, we conclude
that
\[(3.5) \quad \left| \{ \mathcal{F}(K, n) \left| J^{(K)} \geq 2 \right. \right| \right| \leq |\mathcal{F}(K, n - 1)| \]
holds true. But by Theorem 6.10 of [3] we know that
\[|\mathcal{F}(K, n)| = |\mathcal{F}(K - 1, n)| + |\mathcal{F}(K, n - 1)|.\]

Then, necessarily, equation prevails in formula (3.5) and hence there is indeed for every maximal code \( r \) a maximal face that has \( r \) as its reference vector.

q.e.d.

**Corollary 3.3.** Let \( a^* \{ a^{(k)} \}_{k \in K} \) be a nondegenerate family of positive vectors in \( \mathbb{R}^n \). Then, for every \( k \in K \) and every \( i \in I \) there is a bijection \( \mathcal{F}^{(i)} \) which maps

\[ \left\{ F \in \mathcal{F}(K, n) \left| J^{(k)} = 2 \right. \right\} \]
on \( \mathcal{F}^{(-i)} (K, n - 1) := \left\{ F \left| F \text{ is a maximal face of } a^*|_{\mathbb{R}^n \backslash \{-i\}} \right. \right\} \)

This bijection is obtained by associating with any maximal face \( F \) with reference code \( r, \ r_k \geq 2, \) the maximal face on \( \partial \Pi^{(-i)} := \partial \Pi |_{\mathbb{R}^n \backslash \{i\}} \) defined via \( r - e_k \).

**Corollary 3.4.** Let \( \Pi = \sum_{k \in K} \Pi^{(k)} \) be a nondegenerate cephoid. There is a bijection of \( \mathcal{F} := \{ F | F \text{ is a maximal face of } \Pi \} \) onto the set of maximal \((K, n)\)-reference codes, i.e., the set of vectors satisfying (3.1) and (3.2).
4 The Reference Graph

So far we have discussed necessary conditions for maximal face: properties of the reference system, of the adjustment set and the way the adjustment set or the corresponding linear adjustment system determines the normal, provided we are given a maximal face.

Now we investigate sufficient conditions: suppose we are given \( \mathbf{a}^* = (a^{(1)}, \ldots, a^{(K)}) = (a^{(k)})_{k \in K} \) generating the cepheid

\[
\Pi = \Pi^{a^*} = \sum_{k=1}^{K} \Pi^{(k)}
\]

with \( \Pi^{(k)} = \Pi^{a^{(k)}}(k \in K) \). Given a family of subsets of \( I \), say

\[\mathcal{J} = \left( J^{(k)} \right)_{k \in K},\]

we may assign to every index set \( J^{(k)} \) the simplex

\[
\Delta^{(k)} = \Delta^{a^{(k)}} = \text{conv} \left( \{a^{(k,j)}\}_{j \in J^{(k)}} \right) \subseteq \Delta^{a^{(k)}} = \Delta^{(k)}.
\]

What kind of conditions will ensure that these subsimplices are the summands of a maximal face

\[
F = \sum_{k \in K} \Delta^{(k)}_{J^{(k)}}
\]

of the cepheid \( \Pi \)?

In order to specify these conditions it is first of all necessary to exhibit some further properties of a reference system associated to a face. On the other hand we want to treat some of those properties in a more general way. We start out by a definition that lists the obvious requirements.

**Definition 4.1.** Let

\[\mathcal{J} = \left( J^{(k)} \right)_{k \in K}\]

be a family of subsets of \( I \). \( \mathcal{J} \) is called an **admissible system** if the following conditions are satisfied:

1. \( \bigcup_{k \in K} J^{(k)} = I \)

2. \( \sum_{k \in K} |J^{(k)}| = \sum_{k \in K} j_k = K + n - 1. \)

3. For any two different indices \( k, l \in K \) the sets \( J^{(k)} \) and \( J^{(l)} \) contain at most one common index.
4. For every index \( k \in K \) there exists an index \( k' \in K \) with \( k \neq k' \) and 
\[
\left| \left( J^{(k)} \cap J^{(k')} \right) \right| = 1.
\]

Thus, the reference system of a face of a cephoid is clearly admissible.

For every admissible system \( J \) we denote by \( L \subseteq I \) the set of indices that appear in at least two of the members \( J^{(k)} \) of the family. \( L \) is called the set of critical indices (corresponding to \( J \)). Accordingly,

\[
L_k := L \cap J^{(k)}
\]
defines the critical system

\[
\mathcal{L} = \left( L^{(k)} \right)_{k \in K}.
\]

The critical system obviously inherits the defining properties from its parental admissible system, i.e., we have:

1. \( \bigcup_{k \in K} L^{(k)} = L \)
2. For any two different indices \( k, k' \in K \) the sets \( L^{(k)} \) and \( L^{(k')} \) contain at most one common index.
3. For every index \( k \in K \) there exists an index \( k' \in K \) with \( k \neq k' \) and 
\[
\left| \left( L^{(k)} \cap L^{(k')} \right) \right| = 1.
\]

We use this a motivation to define abstract systems \( \mathcal{L} \) with these properties.

**Definition 4.2.** Let \( L \subseteq I \) and let

\[
\mathcal{L} = \left( L^{(k)} \right)_{k \in K}.
\]

be a system of subsets of \( L \). We say that \( \mathcal{L} \) is \( L \)-admissible if the conditions 1., 2., and 3. are satisfied.

Thus, the critical system of an admissible set is \( L \)-admissible with respect to the set \( L \) of critical indices.

We wish to associate a graph to an admissible \( L \)-system as follows.

**Definition 4.3.** The (undirected) associated graph generated by an admissible \( L \)-system \( \mathcal{L} \) is the pair

\[
(\mathcal{L}, \mathcal{E})
\]
given as follows. The nodes of the graph are the elements of the family \( \mathcal{L} \). An edge or arc of the graph is a pair \( E = (L_k, L_{k'}) \) such that \( L_k \cap L_{k'} \neq \emptyset \) holds true. Colloquially we say that \( L_k \) and \( L_{k'} \) are connected if \( E = (L_k, L_{k'}) \) is an edge.
As graph as defined above may have cycles, i.e., in our case a sequence of nodes \( L^{(k_1)}, L^{(k_2)}, \ldots, L^{(k_T)} \) such that, for any \( t \in \{1, \ldots, T - 1\} \) the nodes \( L^{(k_t)} \) and \( L^{(k_{t+1})} \) are connected and \( L^{(k_1)} = L^{(k_T)} \) is the case. We call a cycle \textit{proper} if the same index \( l \in L \) is involved in each edge, i.e., if

\[
L^{(k_t)} \cap L^{(k_{t+1})} = \{l\}
\]

holds true for some \( l \in L \) and all \( t \in \{1, \ldots, T - 1\} \). Otherwise we call the cycle \textit{improper}.

Now we are in the position to proceed with a refinement of our above definition.

**Definition 4.4.** An \( L \)-admissible family of index sets

\[
\mathcal{L} = \left( L^{(k)} \right)_{k \in K}
\]

is called a \textit{pre-adjustment system} if the following conditions are satisfied:

1. \( L := |L| \leq K - 1 \) holds true.
2. \( \sum_{k \in K} |L^{(k)}| =: \sum_{k \in K} L_k = K + L - 1 \).
3. There are at least two indices \( k^*, k^\circ \) such that \( |L^{k^*}| = |L^{k^\circ}| = 1 \) holds true. That is, the associated graph has at least two \textit{boundary nodes}.
4. The associated graph \( (\mathcal{L}, \mathcal{E}) \) is connected.
5. The associated graph \( (\mathcal{L}, \mathcal{E}) \) has no improper cycles.

An admissible family of index sets

\[
\mathcal{J} = \left( J^{(k)} \right)_{k \in K}
\]

is called a \textit{pre-reference system} if the critical set \( L \) induces a critical system \( \mathcal{L} \) that is a pre-adjustment system. The corresponding \textit{linear pre-adjustment system} is the linear system of equations formed in analogy to (1.3) of section 1.

A reference system resulting from a maximal face has the properties listed above. Indeed, a reference system induces a set \( L \) of adjustment indices as well as an adjustment system which is \( L \)-admissible. The associated graph is called the \textit{adjustment graph}. Now we have

**Lemma 4.5.** Let \( F \) be a maximal face of a cepheid \( \Pi = \Pi^a \). Then the adjustment graph has no improper cycles.
Proof: If the graph has an improper cycle, then the linear adjustment system admits of the trivial solution only. More precisely, let (w.l.o.g.)

\[ L^{(1)}, L^{(2)}, \ldots, L^{(\kappa)}, L^{(1)} \]

constitute an improper cycle. Then we find indices \( l_1, l_2, \ldots, l_\kappa \) such that

\[ l_1 \in L^{(1)} \cap L^{(2)}, \ l_2 \in L^{(2)} \cap L^{(3)}, \ \ldots, \ l_\kappa \in L^{(\kappa)} \cap L^{(1)} \]

holds true. Consider the following subsystem of the linear adjustment system, given by

\[
\begin{align*}
    c_1 a_{l_1}^{(1)} &= \lambda_{l_1} \\
    c_2 a_{l_1}^{(2)} &= \lambda_{l_1} \\
    c_2 a_{l_2}^{(2)} &= \lambda_{l_2} \\
    \vdots & \quad \vdots \\
    c_\kappa a_{l_{\kappa-1}}^{(\kappa)} &= \lambda_{l_{\kappa-1}} \\
    c_\kappa a_{l_\kappa}^{(\kappa)} &= \lambda_{l_\kappa} \\
    c_\kappa a_{l_\kappa}^{(1)} &= \lambda_{l_\kappa}.
\end{align*}
\]

(4.6)

This is a system with \( 2\kappa \) variables and \( 2\kappa \) equations. If we write \( a_{jk} := a_{l_j}^{(k)} \) just for the moment, the coefficient matrix is

\[
\begin{pmatrix}
    1 & \kappa & \kappa + 1 & 2\kappa \\
    a_{11} & : & 1 \\
    a_{21} & : & 1 \\
    a_{22} & : & 1 \\
    \vdots & : & \vdots \\
    a_{kk} & : & 1 \\
    a_{1k} & : & 1
\end{pmatrix}
\]

(4.7)

We claim that the matrix (4.7) has full rank. To see this, subtract an \( a_{1k} \)-multiple of the last column from the first column and, thereafter, omit the last column and the last row. Next, add an \( a_{kk} \)-multiple of column \( \kappa \) to column 1. Then, the last row contains the entry \( a_{kk} \) only. Hence (4.7) has full rank if and only if the following matrix (4.8)

\[
\begin{pmatrix}
    1 & \kappa - 1 & \kappa & 2(\kappa - 1) \\
    a_{11} & : & 1 \\
    a_{21} & : & 1 \\
    a_{22} & : & 1 \\
    \vdots & : & \vdots \\
    a_{k-1,k-1} & : & 1 \\
    a_{k,k-1} & : & 1 \\
    a_{kk} & : & 1
\end{pmatrix}
\]

(4.8)
has full rank. By induction, we see that (4.7) has full rank indeed.

q.e.d.

**Lemma 4.6.** Let $F$ be a maximal face of a cephoid $\Pi = \Pi^{o \ast}$. Then the adjustment graph is connected.

**Proof:** The proof runs quite analogously to the one of the previous Lemma 4.5. If the adjustment graph can be decomposed into two disjoint graphs, the each part admits of an independent solution of the linear adjustment system. Hence the solutions span a linear space of dimension at least two – in which case the normal is not uniquely defined up to a constant. A precise version is found in Theorem 2.4. of [5]. q.e.d.

**Lemma 4.7.** Let $F$ be a maximal face of a cephoid $\Pi = \Pi^{o \ast}$. Then the adjustment graph has at least two boundary nodes.

The proof is obvious because the adjustment graph has no improper cycles.

**Corollary 4.8.** Let $a^{\ast}$ be a family of positive vectors. Let $F$ be a maximal face of the corresponding cephoid $\Pi$. Then the reference system defining $F$ is a pre-reference system. The adjustment system is a pre-adjustment system.

Clearly, to any pre-adjustment system that arises from a pre-reference system we may associate the polyhedron

\[ F_L := \sum_{k \in K} \Delta^{(k)}_{L^{(k)}}. \]

Now we have

**Theorem 4.9.** Let $\mathcal{J}_F = (J^{(k)}_{k \in K})$ be a family of subsets of $I$. Then

\[ F = \sum_{k \in K} \Delta^{(k)}_{\mathcal{J}_F^{(k)}} \]

is a maximal face of $\Pi$ if and only if the following holds true.

1. $\mathcal{J}$ is a pre-adjustment system.

2. The solution $(c^{\ast}, \lambda^{\ast})$ to the linear pre-adjustment system of equations satisfies

\[ \begin{align*}
    c^{\ast} a^{(k)}_i &= \lambda^{\ast} (\text{if } (k, l) \in \mathbb{L}) \\
    &\geq c^{\ast} a^{(k)}_i (\text{if } (k, l) \notin \mathbb{L}).
\end{align*} \]

**Proof:** The inequalities in item 2 ensure that the vector $n^{\ast} = \left( \frac{1}{a^{\ast}_1}, \ldots, \frac{1}{a^{\ast}_n} \right)$ constructed via

\[ a^{\ast}_i := \max_{k \in K} c^{\ast} a^{(k)}_i \quad (i \in I) \]

constitutes a linear function that achieves its maximum relative to $\Delta^{(k)}$ exactly on $\Delta^{(k)}_{\mathcal{J}_F^{(k)}}$, thus is a normal to $\Pi$ and, clearly, the normal to $F$. q.e.d.
5 Adjacent Faces: The Normal Cone

The Neighborhood Theorem (3.5. of [3]) describes the shape of the \((n - 2)\)-dimensional subface that is the intersection of two adjacent faces. Based on the duality theory we formulate a generalization. Thereafter we discuss some properties of the normal cone of the \((n - 2)\)-dimensional intersection of two adjacent maximal faces.

**Theorem 5.1.** Let \( \Pi \) be a cephoid and let \( F, \bar{F} \) be adjacent maximal faces (i.e., with \((n - 2)\)-dimensional intersection) with reference systems \( J \) and \( \bar{J} \). Then there exist indices \( p, q \in K, p \neq q \), and \( i_0, i_1 \in I, i_0 \neq i_1 \), with \( i_0 \in L, i_1 \in \bar{L} \), such that the following holds:

\[
J^{(k)} = \bar{J}^{(k)} \quad (k \neq p, q) \\
J^{(p)} = J^{(p)} \cup \{i_0\} \\
\bar{J}^{(q)} = \bar{J}^{(q)} \cup \{i_1\}
\]

**Proof:**

1\textsuperscript{st}\textsc{Step} : As \( F \) and \( \bar{F} \) are neighbors, the intersection is a face

\[
F \cap \bar{F} = \sum_{k \in K} \Delta_{J^{(k)} \cap \bar{J}^{(k)}}^k
\]

with dimension \( n - 2 \), hence

\[
\sum_{k \in K} \left| J^{(k)} \cap \bar{J}^{(k)} \right| = n - 2 + K.
\]

As the corresponding sums for the two faces yield \( n - 1 + K \) we must necessarily find \( p, q \) such that

\[
J^{(p)} = \left( J^{(p)} \cap J^{(p)} \right) \cup \{i_0\} = J^{(p)} \cup \{i_0\} \\
\bar{J}^{(q)} = \left( J^{(q)} \cap \bar{J}^{(q)} \right) \cup \{i_1\} = J^{(q)} \cup \{i_1\}
\]

say,

\[
\begin{array}{cccccc}
J^{(p)} & & & \bar{J}^{(q)} \\
1 & 2 & \ldots & t & i_0 & s & \ldots & r \\
1 & 2 & \ldots & t & s & \ldots & r & i_1
\end{array}
\]

2\textsuperscript{nd}\textsc{Step} : Now \( p = q \) is not possible as we would have \( |J^{(p)}| = |\bar{J}^{(p)}| \). This would imply equal reference vectors for both faces, hence they would coincide. So we know \( p \neq q \).

3\textsuperscript{rd}\textsc{Step} : Now assume that \( i_0 \notin L \) and \( i_1 \notin \bar{L} \) is the case. Then we have \( L = \bar{L} \). As the system \( L \) determines \( F \) uniquely, it would follow...
that $F = \overline{F}$ holds true. On the other hand, assume e.g. $i_0 \in \mathbb{L}, i_1 \notin \overline{\mathbb{L}}$. Then we have $\overline{\mathbb{L}} \subseteq \mathbb{L}$. Now the linear adjustment system of equations is again uniquely attached to $\mathbb{L}$. It follows that all equations corresponding to $\mathbb{L}$ appear in the system attached to $\overline{\mathbb{L}}$ as well. But both systems must have maximal dimension, i.e., generate a solution space of dimension 1. Evidently, the two systems have the same solution space, in which case the normals coincide. Hence again we would find $F = \overline{F}$, which cannot happen. Hence $i_0 \in \mathbb{L}$, $i_1 \in \overline{\mathbb{L}}$ is true indeed.

Finally we check $i_0 \neq i_1$. Consider the reference system of the dual faces, i.e.,

$$J^{(i)} = \{ k \in K | i \in J^{(k)} \}.$$ 

Clearly we have

$$J^{(i)} = J^{(i)} \setminus (i \neq i_0, i_1)$$

(5.5)

$$J^{(i_0)} = J^{(i)} \cup \{ p \}$$

$$J^{(i_1)} = J^{(i)} \cup \{ q \}.$$ 

Therefore we may repeat the argument of the 2nd STEP: if $i_0 = \overline{i_0}$, then the reference vector of the dual faces $F$ and $\overline{F}$ would coincide, which is not possible.

q.e.d.

Obviously formula (5.5) is dual to formula (5.1). For completeness it is useful to state the full consequences.

**Theorem 5.2.** Let $\Pi$ be a cepheid and let $F$, $\overline{F}$ be adjacent maximal faces with reference systems $\mathcal{J}$ and $\overline{\mathcal{J}}$. Then the dual faces are adjacent as well. With the notation in Theorem 5.1, the reference system of the dual faces is given by (5.5).

**Corollary 5.3.** Let $\Pi$ be a cepheid and let $F$, $\overline{F}$ be adjacent maximal faces (i.e., with $(n-2)$-dimensional intersection) with reference systems $\mathcal{J}$ and $\overline{\mathcal{J}}$. Let $i_0, i_1$, and $p, q$ be given by Theorem 5.1. Let $\mathbb{L} = \{(i, s) \in I \times K, i \in K_s, |K_s| \geq 2\}$. Then the normal cone to the intersection

$$F^* = F \cap \overline{F}$$

spans the two-dimensional subspace of $\mathbb{R}^n$ obtained by the projection of the solutions of

$$(5.6) \quad \tilde{a}_s^{(i)} n_i = \mu_s \quad ((i, s) \in \mathbb{L}, (i, s) \neq (i_0, p)) \quad \text{if} \quad |J^{(p)}| \geq 3,$$

or

$$(5.7) \quad \tilde{a}_s^{(i)} n_i = \mu_s \quad ((i, s) \in \mathbb{L}, (i, s) \neq (i_0, p), (i_5, p)) \quad \text{if} \quad |J^{(p)}| = \{i_0, i_5\}.$$
The proof is obvious in view of Remark 2.6. Note that with respect to the equations (2.24), for $|J^{(p)}| = 2$ one has to cancel two equations and the variable $\mu_p$, while otherwise one has just to cancel one equation.

**Corollary 5.4.** If $|J^{(p)}| = 2$, and $J^{(p)} = \{i_0, i_9\}$, then either $i_9 \in L$ or $i_9 = i_1$.

For, $i_9$ has to appear in some $J^{(s)}$ with $|J^{(s)}| \geq 2$.

**Corollary 5.5.** Let $F$ be a maximal face of a cephood $\Pi$ with reference system $\mathfrak{J}$ and normal $n$. For some $p \in K$, let $|J^{(p)}| \geq 2$ and let $i_0 \in J^{(p)}$, $i_0 \notin L$. Define

$$F^* := \sum_{k \in K - p} \Delta_j^{(k)} + \Delta_j^{(p)}_{\{i_0\}}.$$  

Then $F^* \subseteq \partial \Pi^{(-i_0)}$ and the second extremal to the normal cone of $F^*$ is $n^* = n - n_{i_0}e^{i_0}$.

**Proof:** Check that $n^*$ obeys the equations of Corollary 5.3, specified for $F^*$ respectively.

q.e.d.

**Theorem 5.6.** Let $F$ be a maximal face of a cephood $\Pi$ with reference system $\mathfrak{J}$. For some $p \in K$, let $|J^{(p)}| \geq 2$ and let $i_0 \in J^{(p)} \cap L$. Let

$$F^* := \sum_{k \in K - p} \Delta_j^{(k)} + \Delta_j^{(p)}_{\{i_0\}}.$$  

Then there is some maximal face $\overline{F}$ of $\Pi$ such that

$$F^* = F \cap \overline{F}.$$  

**Proof:** The normal cone to $F^*$ is described by Corollary 5.3. Let $\overline{n}$ be the second extremal of this cone. By the nondegeneracy assumption, this extremal can either have exactly one zero coordinate $\overline{n}_i$ (in which case $F^*$ is located in the corresponding $\partial \Pi^{(-i)}$), or else it is positive. In the latter case the theorem is verified.

Hence, whenever $s \neq p$ and $|J^{(s)}| \geq 2$, then $\bar{\mu}_s > 0$, for otherwise the equation

$$\bar{\alpha}_s^{(s)} \overline{n}_i = \bar{\mu}_s \quad (i \in J^{(s)}),$$  

would result in two zero coordinates of $\overline{n}$ at least. If $|J^{(p)}| \geq 3$, then the same argument holds true for $p$: we would have at least two equations of the type (5.10), namely for $i \in J^{(p)} = \{i \in J^{(p)}, i \neq i_0\}$. Therefore, it remains to study the case suggested by equations (5.7), where $\hat{i}_0$ is the second index in $J^{(p)}$. Now, if $\overline{n}_{\hat{i}_0} = 0$, then $F^*$ would be located in $\partial \Pi^{(-i_0)}$, contradicting the fact that $i_0 \in L$ and nondegeneracy. If, on the other hand $\overline{n}_{\hat{i}_0} = 0$ holds
true, then it is seen at once that $\bar{n}$ satisfies the equations of Corollary 5.3 with respect to

$$F^{**} := \sum_{k \in K - \{k\}} \Delta^{(k)}_{J(k)} + \Delta^{(p)}_{J(p) \setminus \{i_0\}},$$

which again contradicts nondegeneracy. Hence, $\bar{n}$ is indeed positive and hence the normal of an adjacent face.

\textbf{q.e.d.}

\textbf{Theorem 5.7.} Let $r$ be a reference vector and let $F$ be the unique corresponding face. Then, for every $k \in K$ with $r_k \geq 2$, there exists uniquely some $\bar{k} \in K$, $\bar{k} \neq k$, such that the face $F$ corresponding to $\bar{r} := r + e^{\bar{k}} - e^k$ is adjacent to $F$.

\textbf{Proof:} We know that $J^{(k)} \cap L \neq \emptyset$ for every $k \in K$. Hence, whenever $|J^{(k)}| \geq 2$, we can pick some $i_0 \in J^{(k)}$ that satisfies the conditions of Theorem 5.6. Applying Theorem 5.6 we find at once that the reference vector of the adjacent face $\bar{F}$ has the required property.

\textbf{q.e.d.}
6 Generalized Tentacles

Within this section we describe the generalized version of the tentacle system (see Corollary 4.6 of [3]). The tentacle system exhibited in [3] refers to the prisms involved in the construction of a cephoid. For each such prism a translate appears on the Pareto surface \( \partial \Pi \). This translate is the center of a system of arms connecting it with each boundary \( \partial \Pi_{1,R^n \{i \}} \) via a system of cylinders.

Now we shall show that every maximal face generates a tentacle system. By this we mean a well defined system of maximal faces connected by the adjacency relation.

For a start, we fix some maximal face \( F \) identified by its reference vector \( r \). Also, we specify a fixed member of the family \( a^* \), say \( a^K \). Of course, any other element of \( K \) could play the role of \( K \).

**Definition 6.1.** Let \( a^* \) be a nondegenerate family of positive vectors, let \( F \) be a maximal face of \( \Pi \) and \( r \) the corresponding reference vector. Suppose that \( r_K \geq 2 \) holds true.

1. The reference vectors

\[
(6.1) \quad r - e^K + e^k \ (k \in K)
\]

are called the **tentacle-codes** or **T-codes** of \( F \).

2. The corresponding maximal faces \( F_{-K,+k} \) are called the **tentacle-faces** \( T \)-faces of \( F \).

3. The \( n-2 \) dimensional face of \( \partial \Pi^{(-i)} := \partial \Pi_{1,R^n \{i \}} \) corresponding to the reference vector \( r - e^K \) is denoted by \( \mathcal{P}(F) \).

4. An \( n-2 \)-dimensional subface \( F^0 \) of a \( T \)-face with reference vector \( r - e^K \) is called a **cylinder basis**.

Our aim is to show that the family of \( T \)-faces constitute a simple connected graph without circles which terminates exactly on the \( (n-2) \)-dimensional boundary of \( \partial \Pi \).

**Lemma 6.2.** There are \( K \) different \( T \)-faces including \( F = F_{-K,+K} \). For any \( i \in I \), \( \partial \Pi^{(-i)} \) is the outer surface of the cephoid generated by \( a^* \big|_{I_{-i}} \) and there exists a \( T \)-face \( F \) of \( \Pi \) such that \( F \cap R^{I_{-1}} \subseteq \partial \Pi^{(-i)} \) is a cylinderbasis.

**Proof:** The first statement is obvious. The second one follows from the Coincidence Theorem (Theorem 3.1. of [3]), item 2 (d) and by Corollary 3.3 as \( \mathcal{P}(F) \) is the desired cylinderbasis on the boundary \( \partial \Pi^{(-i)} \).

\( \text{q.e.d.} \)
Lemma 6.3. Let \( F^{-K,+l} \) be a \( T \)-face. Then the number of \((n-2)\)-dimensional subfaces of \( F^{-K,+l} \) that are cylinder bases is at least 2. More precisely, the number of such subfaces is

\[
\begin{align*}
r_K & \geq 2, \quad \text{for } l = K, \text{ i.e., for } F = F^{-K,+K} \\
r_l + 1 & \geq 2, \quad \text{for } l \neq K
\end{align*}
\]

Proof: Consider the case \( l \neq K \). Let \( \{ \widehat{J}^{(k)} \}_{k \in \mathbb{K}} \) denote the reference system of \( F^{-K,+l} \). Then \( |\widehat{J}^{(l)}| = r_l + 1 \geq 2 \) holds true. For every \( i_0 \in \widehat{J}^{(l)} \) the system

\[
\{ \widehat{J}^{(k)} \}_{k \in \mathbb{K} - l}, \quad \widehat{J}^{(l)} - i_0
\]

constitutes a reference system defining an \((n-2)\)-dimensional subface of \( F^{-K,+l} \) which obviously is a cylinder basis.

q.e.d.

Lemma 6.4. Let \( F^{-K,+l} \) be a \( T \)-face and let \( \widehat{F}^0 \) be an \((n-2)\)-dimensional subface that is a cylinder basis. If \( i_0 \in I \) is not an adjustment index in the reference system of \( F^{-K,+l} \) and \( i_0 \) does not appear in the reference system of \( \widehat{F}^0 \) (cf. formula (6.3)), then \( \widehat{F}^0 \subseteq \partial \Pi^{(-i_0)} \), i.e., \( \widehat{F}^0 = \mathcal{P}^{i_0}(F) \) is the image of \( F \) in \( \partial \Pi^{(-i_0)} \) under the bijective mapping established in Corollary 3.3.

Proof: If an index \( i_0 \) does not appear in the reference system of an \((n-2)\)-dimensional subface, then there is no summand of any \( \Pi^{(k)} \) contributing to the \( i_0 \)-coordinate, hence this coordinate vanishes for all elements of \( \widehat{F} \).

q.e.d.

Lemma 6.5. Let \( \widehat{F} = F^{-K,+k} \) and \( \widehat{F} = F^{-K,+l} \) be different \( T \)-faces. Let \( J^{(K)}, \widehat{J}^{(K)} \) denote the reference set corresponding to \( \Pi^{(K)} \). If \( |J^{(K)} \setminus \widehat{J}^{(K)}| \geq 2 \) or \( |J^{(K)} \setminus \widehat{J}^{(K)}| \geq 2 \) holds true, the \( \widehat{F} \) and \( F \) are not neighbors.

Proof: Obvious by the Neighborhood Theorem (Theorem 3.5 of [3]).

q.e.d.

Definition 6.6. The \( T \)-graph of \( F \) (with respect to \( K \)) is the graph

\[
\Gamma = (V, E)
\]

with nodes \( V = \{ T \text{-faces} \} \) and edges \( E = \{ \text{cylinder bases common to two } T \text{-faces} \} \).

Note that two nodes are connected by an edge if the cylinder basis is a joint \((n-2)\)-dimensional subface of both faces. A \( T \)-face is called terminal if, for some \( i \in I \), the intersection \( F \cap \partial \Pi^{(-i)} \) is a cylinder basis. \( F \cap \partial \Pi^{(-i)} \) is called the \( i \)-th boundary cylinder basis.

Theorem 6.7. The \( T \)-graph \( \Gamma \) of \( F \) (w.r.t. \( K \)) is a simple connected graph without cycles, that is, a tree. For every \( i_0 \in I \) there is a unique path from \( F \) to a terminal node which contains the boundary cylinder basis \( \mathcal{P}^{i_0}(F) \).
**Section 6: Generalized Tentacles**

Proof: 1st STEP:

Let

\[ F = \sum_{k=1}^{K} \Delta_{J^{(k)}} \]

with \( r_k = |J^{(k)}| \ (k \in K) \) and \( r_K \geq 2 \). First of all we consider the case that \( i_0 \in J^{(K)} \) holds true. Then the \((n-1)\)-dimensional subface

\[ \hat{F}^{i_0} = \sum_{k=1}^{K-1} \Delta_{J^{(k)}} + \Delta_{J^{(K)} - i_0} \]

is a cylinder basis. This basis is a boundary basis if \( i_0 \not\in L \). If so, we are done.

2nd STEP:

If \( \hat{F}^{i_0} \) is not a boundary basis, then \( i_0 \in L \). According to Theorem 5.6 and Theorem 5.7, there is an adjacent face, say \( F = F^{-K,+\kappa} \). The reference system at position \( K \) consists of the index set \( J^{(K)} \setminus \{i_0\} \) and at position \( \kappa \) of, say, \( J^{(\kappa)} \cup \{i_1\} \). In view of the Neighborhood Theorem, we have \( i_1 \in L \).

3rd STEP:

If it so happens that \( i_0 \in J^{(\kappa)} \), then we proceed as in the first step. We remove \( i_0 \) from \( J^{(\kappa)} \) and add a suitable index to some \( J^{(\gamma)} \). We have again reached a \( T \)-face \( \tilde{F} \) with the number of appearances of \( i_0 \) reduced by 1.

4th STEP:

Suppose that \( i_0 \in J^{(\kappa)} \) does not hold. Then we focus on \( i_1 \in J^{(\kappa)} \cap L \) as specified in the 3rd STEP. We can remove \( i_1 \) (and possibly further indices) from \( J^{(\kappa)} \) and add another index to some \( J^{(\lambda)} \) and so on. If there are more indices feasible besides \( i_1 \), then two or more paths will branch off at the node reflected by \( F \).

The path can never return to \( F \) because any other path leaving \( F \) is characterized by a missing index \( i_0 \neq i_0 \) instead of \( i_0 \). No face with missing index \( i_0 \) is a neighbor to a face with missing index \( i_0 \) by Lemma 6.5. By a similar argument, the path cannot return to another face met during the construction.

Of course, when our path branches off, then we can follow all branches.

As there are only finitely many \( T \)-vectors, we must eventually reach some face \( \tilde{F} \) with a reference vector \( \tilde{r} \) that is a \( T \)-code and yields \( \tilde{r}_\nu = r_\nu + 1 \) at some coordinate \( \nu \) with \( i_0 \in J^{\nu} \). Then we can again reduce the number of appearances of \( i_0 \) by one.

5th STEP:
Obviously we can proceed in this way, reducing the appearances of \( i_0 \) step by step until \( i_0 \notin L \) is the case. Then we have found a face with cylinder basis \( \mathcal{P}_0 \). The path constructed in the \( T \)-graph connects \( F \) and \( \mathcal{P}_0 \).

**6th Step**:

On the other hand, we may consider some \( \mathcal{P}(F) \) which corresponds to a unique face of \( \Pi_{\mathcal{E}^n} \). This face can be uniquely extended to a face \( \tilde{F}^i \) of \( \Pi \) (the set \( L \) is the same for both and characterizes both faces). Starting the procedure explained above, we can connect \( \mathcal{P}(F) \) with every \( \mathcal{P}(F) \) for \( i \in I, i \neq i \). Thus the \( T \)-graph has boundary nodes at each \( \partial \Pi^{(i)} \), all of them being connected without loops and circles.

q.e.d.

**Example 6.8.** The cephoid “FourFour” is a sum of four prisms in four dimensions. It is given by the matrix

\[
(6.4) \quad A = \begin{pmatrix}
701 & 502 & 303 & 104 \\
205 & 116 & 1007 & 128 \\
139 & 110 & 611 & 512 \\
67 & 230 & 444 & 777 \\
\end{pmatrix}
\]

Figure 6.1 shows the canonical representation within the simplex \( 4 \Delta^0 \).

![Figure 6.1: The canonical representation of FourFour](image)

In the following we describe maximal faces by their reference systems. Con-
sider the block without yellow edges

\begin{equation}
B^y : \begin{array}{cccc}
\text{blue} & \text{red} & \text{green} & \text{yellow} \\
12 & 13 & 24 & 2 \\
\end{array}
\end{equation}

the reference vector of which is \((2, 2, 2, 1)\). We choose the cylinder bases suggested by the reference vector \((2, 1, 2, 1)\). The block \(B^y\) has the square \(T^3\) as the cylinder basis at \(\partial \Pi^{(3)}\) (the left front side of the tetrahedron). The adjacent face is the cylinder that consists of a green triangle and a blue line segment; it is given by

\begin{equation}
Z_{gr,b} : \begin{array}{cccc}
\text{blue} & \text{red} & \text{green} & \text{yellow} \\
12 & 3 & 234 & 2 \\
\end{array}
\end{equation}

Note that the intersection \(B^y \cap Z_{gr,b}\) has the correct reference code \((2, 1, 2, 1)\).

At \(Z_{gr,b}\) the path has two branches, the boundary basis \(P^4\) at the lower subsimplex is part of the cylinder. If we follow the second path, we reach block without red. This one is difficult to recognize, it consists of three line segments of blue, green, and yellow color and is described by

\begin{equation}
B^r : \begin{array}{cccc}
\text{blue} & \text{red} & \text{green} & \text{yellow} \\
12 & 3 & 34 & 24 \\
\end{array}
\end{equation}

The final face is the cylinder consisting of a blue triangle and a green line segment. It is described by

\begin{equation}
Z_{b,gr} : \begin{array}{cccc}
\text{blue} & \text{red} & \text{green} & \text{yellow} \\
123 & 3 & 34 & 4 \\
\end{array}
\end{equation}

This cylinder has subfaces \(P^1\) (at the right front side) and \(P^2\) (at the rear side of the tetrahedron), thus we have found all \(P^i, i \in K\).
Figure 6.2 shows the “tentacle” described by the above sequence. The four maximal faces have been isolated from Figure 6.1. The basis in each face consists of a square with blue and green parallel sides.
