Abstract

In this paper, we analyze the dynamics of a very small economy which tries to attract foreign investments. For that purpose, we model the intertemporal behavior of a small jurisdiction using taxes and attractive public infrastructures as policy instruments, for given policy choices of the rest of the world. Applying Pontryagin’s maximum principle, we then characterize the potential steady states which are attainable. These results give some insights into the policy behavior that may guarantee the long run survival of very small economies.

Keywords: public goods competition, spatial competition, foreign direct investments, country size.

JEL classification: H25, H73, F13, F15, F22.

1 Introduction

Small states suffer from very limited capital and labour resources both in amount and in variety. Their small home market size prevents them from exploiting scale and scope economies. It is therefore not surprising that small states are highly open to international trade and capital flows.

Because of their smallness these countries are highly depending on forces outside their control which could threaten their economic viability (Briguglio, 1995). This explains the general view that the economic performance of these small states is associated with vulnerability\(^1\) to external shocks. Nevertheless, the strong growth performance of some small states suggests that it is possible to at least partially offset this vulnerability and increase their resilience by means of appropriate endogenous policies (Armstrong and Read, 2002). Armstrong, De Kervenoael and R. Read (1998) show that one country’s economic smallness does not necessarily have a negative effect on its performance. This can be explained by the fact that small countries develop abilities and use instruments to overcome their natural handicaps. For example, some of the richest countries in the world are small states such as Luxembourg, and Iceland\(^2\). This is an illustration of what Briguglio et al. (2009) call the “Singapore Paradox”, which is the situation where a country highly vulnerable to exogenous shocks still manages to attain high economic performance.

Since domestic capital is relatively scarce in very small economies, it follows that attracting foreign investments is an important way to fill in this gap. As a matter of fact those economies tend to get more private capital from abroad as a ratio of total capital formation (Streeten, 1993). Moreover, capital inflow may also be a critical contributor to the growth and development of small states (Read, 2008).

\(^1\)Economic vulnerability indices mostly depend on a high level of openness and therefore are typically associated with smallness. The Commonwealth Secretariat and the UN has developed complex and rigorous vulnerability indices (Armstrong and Read, 2002).

\(^2\)Note that high vulnerability and good economic performance are not contradictory aspects of very small economies. Indeed, Iceland has been an example for good economic performance but has shown great fragility in the context of the latest financial crisis.
In this paper, we assume that the small country tries to attract foreign investments through low taxes and/or high level of public goods, which enhance firms’ productivity. Public goods can cover a wide range of infrastructures, services and regulations provided by the local and/or the central government are attractive to firms if they enhance their productivity. Accordingly, capital locates according to differentials in offered public good levels and tax differentials.

The literature has investigated the role of jurisdictions’ size on their capacity to attract capital. Recent papers show that small economies can be attractive not only for tax reasons but also for their provision of public infrastructures (Justman et al., 2005, Zissimos and Wooders, 2008, Hindriks et al., 2008, Pieretti and Zanaj, 2009).

This paper extends this literature by modelling the dynamics of a small economy’s strategies to attract foreign investments. More precisely, we study a small state’s inter-temporal choice of optimal taxes which are used to afford public goods which enhance firms’ productivity. Applying Pontryagin’s maximum principle we then characterize the potential steady states attainable by the small economy.

The dynamic interactions among jurisdictions to attract mobile factors have already been analyzed using the framework of repeated games. The main issue studied by this literature is the tax coordination problem between symmetric regions (Cardarella et al., 2002, Catenaro and Vidal, 2006, Itaya et al., 2008). The purpose of this paper is however not to model a game between jurisdictions. We rather focus on the strategic choices of a very small open economy facing exogenously given choices of the rest of the world. The world is thus divided into two unequal sized regions where size

---

3In this context, we may consider transportation infrastructures, universities and public R&D investment, but also property rights enforcement, capital market regulations, labor and environmental regulations and the absence of red tape procedures. It follows that countries’ ability to attract foreign investment may also be attractive for the quality of their institutions. In the Oxford Handbook of Entrepreneurship (2007), it is argued that the abundance of entrepreneurs in a country depends, among other factors, on the existence of regulations, property rights, accounting standards and disclosure requirements. Furthermore, in recent years there has been a surge of country and cross-country studies relating economic development to institutions, especially those affecting capital market development and functionality (La Porta et al. (1997) among others).
refers to the magnitude of the population, which coincides with the number of capital-owners who are simultaneously entrepreneurs and workers. More basically, our paper tries to offer an insight into the dynamic policy behavior of a very small country trying to guarantee the long run survival of its economy. We thus analyze, in an infinite time horizon, the dynamics of its size and its policy instruments for exogenous foreign levels of taxes and public goods. In that context we will have to deal with complex state space conditions.

The main findings of the paper can be summarized as follows.

We show that there exists three types of steady states. One in which the size of the initially small country attracts sufficiently external capital to grow as big as the foreign economy. One in which the small economy is no more economically viable since it looses all its productive capital. Finally an intermediate situation in which the domestic economy survives while remaining small. In this scenario, there exists at least one intermediate steady state which exhibits saddle point stability. If the small economy does not undergo the optimal path which leads to one of these intermediate equilibria it may converge to the worst case. The survival of the small economies is thus an important public policy issue which implies an appropriate choice of initial conditions and a dynamic update of the tax policy.

The paper is organized as follows. The next section presents the model and the optimal conditions via Pontryagin maximum principle. Section 3 provides the type and the analysis of steady states and its convergence. Finally section 4 concludes.

2 The model

The world is composed of two regions of unequal population size⁴. In the rest of the paper, we consider the smallest region as the small or the home country and the largest as the foreign country or the rest of the world indifferently. We assume that the mem-

---

⁴Country size may be defined by its population, by its area, or by its national income (Streeten, 1993). In our paper, we focus on the population aspect rather than on the spatial size.
bers of both jurisdictions are at the same time entrepreneurs and workers and each of them owns one unit of productive capital\(^2\). We thus assume that the size of a country is equivalent to the number of firms located in its territory.

At time \(t = 0\), these jurisdictions are represented on an interval \([-S(0), S^*(0)]\).\(^6\) The size of the small country is \(S(0)\) and extends from \(-S(0)\) to 0 which corresponds to the border \(B\). The rest of the world has a size of \(S^*(0)\) with \(S(0) < S^*(0)\) and extends from 0 to \(S^*(0)\). The firm-owners in both jurisdictions are evenly distributed on their respective sub-interval according to their disposition to invest outside their home location. As in Ogura (2006), we assume that the population of investors is heterogeneous in the degree of their attachment to home\(^7\).

In our spatial setting we assume that the closer firms are located to the extremes the more they are attached to their current location. Conversely, the closer firms are to the border 0, the less they are attached to their territory and the easier they are able to relocate\(^8\) abroad. This means that a firm of type \(\alpha \in [-S(0), 0]\) located in the home country incurs a disutility of relocating abroad which equal \(k \cdot x\), where \(x = d(\alpha, 0)\), i.e. the distance between 0 and \(\alpha\). The coefficient \(k\) represents the unit cost of moving capital abroad which can also be interpreted as the degree of international integration.

Now assume that each population member of both jurisdictions owns one unit of capital which she combines with her labor to set up a firm to produce \(q + a_i\) \((a_i = a, a^*)\) units of a final good, where \(q\) is the private component of (gross) productivity. The fraction \(a\) \((a^*)\) of the produced good depends on the public input\(^9\) supplied by the home

\(^5\)We thus implicitly assume that the endowment in human resources and physical capital grows in proportion to the human population.

\(^6\)The substrict “*” refers to the large (foreign) jurisdiction.

\(^7\)Heterogeneity in home attachment was first considered in the fiscal competition literature by Mansoorian and Myers (1993).

\(^8\)For reasons of simplicity, we assume that relocation if any is only possible in the neighboring jurisdiction.

\(^9\)The public input satisfies the local public good characteristic, which means that it is jointly used without rivalry by firms located in the same jurisdiction. It follows that the benefits and the costs of
(foreign) jurisdiction. The produced output is sold in a competitive (world) market at a given price normalized to one. Assuming that both countries have equal access to a common market implies that the homiest jurisdiction does not suffer from a reduced home market. We further suppose that the unit production cost is constant and equal to zero without loss of generality. For example, the public infrastructure investment $a_i$ may be an improvement of existing regulations that potentially increase the performance of the financial services industry. This makes, other things being equal, the country more attractive to foreign financial firms and increases the attachment to home of domestic financial firms.

We now adopt a temporal perspective of the above setting. Each period $t \in [\Delta t, +\infty)$, (for any $\Delta t > 0$) governments update their choice in terms of offered public goods and taxes\(^{10}\). We assume that the total number of entrepreneurs, $S(t) + S^*(t)$ will be constant over time $t$ and normalized to one. Since firms will move, the relative size of both jurisdictions will change with $t$. In the following we wish to focus on the behavior of a small country. We therefore suppose that the home country’s size $S(t)$ is small enough to consider the rest of the world’s choices as exogenously given. We thus keep in mind following state constraint

$$0 \leq S(t) < \frac{1}{2} \text{ for } t \in [0, +\infty). \tag{1}$$

Providing firms with public infrastructures is costly. The public technology which serves to produce each period the public input is given by the function $f(S(t), T(t))$. where $T(t) \in [0, \hat{T}]$ denotes the tax levied on one unit of capital at time $t$, and $\hat{T} \in (0, \infty)$ is a constant. Supposing that the public good depreciates at a rate $\delta$, we can write the these good only accrue at the jurisdictional level. As in Zissimoss and Wooders (2008), we shall abstract from congestion costs. Taking account of congestion would complicate our framework without improving qualitatively the results. Moreover, if the public input represents immaterial goods as law and regulations (protecting intellectual property, specifying accurate dispute resolution rules,...), the absence of congestion is easily justified by the particular nature of these goods.

\(^{10}\)Notice that we assume there are no sunk cost on the investment or that our unit of time $t$ is long enough to cancel the sunk cost of investment.
following motion equations

\[ \dot{a}(t) = h[a(t)] - \delta a(t) + f[S(t), T(t)], \quad (2) \]

\[ \dot{a}^*(t) = h[a^*(t)] - \delta a^*(t) + f[S^*(t), T^*(t)], \quad (3) \]

where \( h[\ldots] \) represents the flow of public inputs produced by the use of public inputs. For simplicity we shall work with following linear functions:

\[ h[a(t)] = \xi a(t), \quad h[a^*(t)] = \xi a^*(t), \quad f[S(t), T(t)] = \zeta S(t)T(t) \quad \text{and} \quad f[S^*(t), T^*(t)] = \zeta S^*(t)T^*(t) \]

where \( \xi \) is a non-negative unit fee charged for the use of the public infrastructure and \( \zeta \) represents a non-negative productivity factor. Furthermore, we assume that these coefficients verify \( 0 \leq \xi < \delta \) which rules out a breakdown in the production of public infrastructures.

Assume now that an entrepreneur of type \( \alpha(t) \) initially located in the small country considers to stay at home or to invest her/his physical capital abroad. If she/he decides not to move, her/his profit is given by\(^{11}\)

\[ \pi(t) = q(t) + a(t) - T(t) \quad (4) \]

If she invests abroad, her/his profit becomes

\[ \pi^*(t) = q(t) + a^*(t) - T^*(t) - k \cdot x(t) \]

Furthermore, consider that this capital-owner is indifferent between investing abroad and staying at home. Then it follows that

\[ q(t) + a(t) - T(t) = q(t) + a^*(t) - T^*(t) - k \cdot x(t). \]

After setting \( b^*(t) = \frac{a^*(t) - T^*(t)}{k} \), we obtain

\[ x(t, a, a^*, T, T^*) = \left[ b^*(t) - \frac{a(t) - T(t)}{k} \right]. \quad (5) \]

In other words, the foreign country attracts capital \( (x > 0) \) from the small jurisdiction if the net gain of investing abroad, i.e. \( a^*(t) - T^*(t) \), is higher than the net gain of staying at home, \( a(t) - T(t) \), after taking into account the mobility cost.

\(^{11}\)For sake of simplicity, we assume that \( q \) is such that the profit of each firm is positive for all equilibrium level of public goods and taxes.
The motion equation of the size variable $S(t)$ of the small economy is given by

$$
\dot{S}(t) = -\rho x = \rho \left( \frac{a(t) - T(t)}{k} - b^*(t) \right),
$$

(6)

with the initial condition $\frac{1}{2} > S(0) > 0$ and positive constant $\rho$ some kind of density function, which does not affect the analysis and results. Remember that we assumed that the home country is so small that it faces exogenously given levels of capital tax $T^*(t)$ and public infrastructure $a^*(t)$ chosen by the foreign country.

Note that the relocation of a subset of firms modifies at each period alters the ranking of firms’ attachment to home. In the following we adopt the following rule. For all $\tilde{\alpha}(t) \in [-S(t), S^*(t)]$, we define $\tilde{\alpha}(t) = \tilde{\alpha}(t-\Delta t) + x$, where $\tilde{\alpha}(t) = \begin{cases} 
\alpha(t) \in [-S(t), O(t)] & 
\alpha^*(t) \in [O(t), S^*(t)]
\end{cases}$

and $O(t)$ stands for the origin at period $t$.

We thus assume that the preferences for the home location will change according to the relative attractiveness of the competing jurisdictions in the following way. For the firms which don’t move, attachment to home will increase by $x$ if the small economy is attractive to foreign investors ($x < 0$) and it will decrease if the foreign location attracts capital from the small country ($x > 0$). For the capital owners who relocate abroad, the attachment to the new location decreases with the attachment they had to the country they left.

In the rest of the paper we focus on the small jurisdiction. We analyze, in an infinite time horizon, the dynamics of its size $S(t)$ and its policy instruments $T(t)$ and $a(t)$ for exogenous foreign levels of taxes ($T^*$) and public goods ($a^*$). We thus consider that the rest of the world does not react to the small country’s decisions. We also analyze the convergence of the variables $S(t)$, $T(t)$ and $a(t)$ towards possible steady states.

We further assume that policy makers maximize the discounted linear-quadratic utility, which depends on tax revenues, $S(t) \cdot T(t)$ net of the adjustment cost of public inputs $a^2(t)$ with unit adjustment cost $\frac{\beta}{2} > 0$. The objective-function of the small

---

12The time preference parameter $r$ increases with the degree of “impatience” of the home country’s population.
economy is given by
\[
\max_{T(t)} \int_0^\infty e^{-rt} \left[ S(t)T(t) - \frac{\alpha}{2} (S(t)T(t))^2 - \frac{\beta}{2} a^2(t) \right] dt,
\]
subject to the state equations (2) and (6) and the state constraint (1), where \( \alpha \) represents an cost parameter of collecting taxes. We assume furthermore that linear-quadratic utility is increasing and concave in term of total tax, that is, \( \hat{T} < \frac{1}{2\alpha^2} \).

We now characterize the inter-temporal optimal tax strategy chosen by the policy makers in the small country. Applying Pontryagin’s maximum principle, we derive a canonical system of ordinary differential equations that has to be satisfied by the optimal trajectories. Since the Hamiltonian of the dynamic optimization problem is concave with respect to the state variables, the Maximum principle provides not only necessary but also sufficient optimality conditions for interior solutions (see e.g. Sethi and Thompson [16], Hartl et al. [9], or Chiang [7]).

**Proposition 1** For any state trajectory \((S(t), a(t))\) that corresponds to an optimal taxation strategy of the policy maker, there exist piecewise absolutely continuous costates \(\mu(t), \nu(t)\) and two multipliers \(\theta_1(t) \geq 0, \theta_2(t) \geq 0\), such that the optimal choice variable \(T(t)\) satisfies
\[
T(t)S^2(t) = \frac{(1 + \zeta \nu)S - \xi(\mu - \theta_1 + \theta_2)}{\alpha_2}.
\]

In addition to (6) and (2) the costate equations become
\[
\dot{\mu} = r\mu - \zeta T \nu - (1 - \alpha T S)T, \quad (9)
\]
\[
\dot{\nu} = (r + \delta - \xi) \nu + \beta a - \frac{\rho}{k} (\mu - \theta_1 + \theta_2). \quad (10)
\]

We further have
\[
\dot{S} = -\rho \left( b^* - \frac{a - T}{k} \right) \leq 0, \text{if } S(t) = \frac{1}{2}; \quad \theta_1(t) \left( \frac{1}{2} - S(t) \right) = 0, \theta_1 \geq 0, \quad (11)
\]
\[
\dot{S} = -\rho \left( b^* - \frac{a - T}{k} \right) \geq 0, \text{if } S(t) = 0; \quad \theta_2(t)S = 0, \theta_2 \geq 0. \quad (12)
\]

Finally, the transversality conditions \(\lim_{t \to \infty} e^{-rt} \mu S = 0\) and \(\lim_{t \to \infty} e^{-rt} \nu a = 0\) are satisfied.
In the following section, we characterize the potential steady states of the system and we analyze how the steady states can be attained.

3 Steady states and convergence analysis

Steady states are defined as rest points of the dynamic equations (2), (6), (9) and (10) with assumption that in the long run $a^*$ and $T^*$ are constants. Due to the state space constraints, there are two types of possible steady states: two constraint steady states and unconstraint steady state(s). The constraint steady states can be the upper bound, $\bar{S} = \frac{1}{2}$, of the small’s country population or its lower bound $\underline{S} = 0$.

We first study the interior steady states $\hat{S}$ ($0 < \hat{S} < \frac{1}{2}$) where the boundary constraints are both not binding. Hence, $\hat{\theta}_1 = 0$ and $\hat{\theta}_2 = 0$ and the interior rest points of the dynamic system (6), (2), (9) and (10) are specified in the following proposition 13.

Proposition 2 For any given parameters $\rho$, $\delta$, $\xi (< \delta)$, $\zeta$, $k$, and for any foreign policy choices, $a^*$ and $T^*$, made by the rest of the world, there is always one steady state 14

$$\hat{a} = \frac{\zeta(r + \delta - \xi)}{\alpha(r + \delta - \xi)(\delta - \xi) + \beta \xi^2} (> 0), \quad \hat{S} = \frac{(\delta - \xi)\hat{a}}{\zeta \hat{T}}, \quad \hat{T} = \hat{a} - (a^* - T^*)$$

(13)

and the two costate variables are

$$\hat{\mu} = 0, \quad \hat{\nu} = -\frac{\beta \hat{a}}{(r + \delta - \xi)} (< 0).$$

(14)

This steady state is a saddle point of the canonical system (2), (6), (9) and (10). Moreover, it is one dimensional locally asymptotically stable, if $r > \frac{\rho \hat{T}}{k \hat{S}}$. Otherwise, if $r < \frac{\rho \hat{T}}{k \hat{S}}$, it is two dimensional locally asymptotically stable.

13 The proof is given in the appendix

14 In addition to the above interior steady state, other interior solutions may appear for special parameter and coefficient combinations. We present these cases in the appendix.

15 The values of $\hat{T}$ and $\hat{S}$ are given in (13).
First note that according to (13) it is optimal for the small state to equate the net (of taxes) amount of provided public goods $\hat{a} - \hat{T}$ to that of the foreign economy ($a^* - T^*$). It also appears in (13) that the amount of public infrastructure offered in the steady state does not depend on the rest of the world’s decision variables. This is not the case for the equilibrium tax rate $\hat{T}$ and consequently for the equilibrium size $\hat{S}$.

If the policy variables set by the rest of the world change, the budget condition in the small open economy always holds. This follows from the fact that we always have $(\delta - \xi)\hat{a} = \zeta \hat{S} \hat{T}$ since $\dot{a} = 0$. This implies that the tax revenue $\hat{S} \hat{T} = \frac{(\delta - \xi)\hat{a}}{\zeta}$ is independent of the foreign decision variables. It follows that the costate variable corresponding to $S$ is zero in the steady state, $\hat{\mu} = 0$. Furthermore, the negative value of $\hat{\nu}$ implies that increasing the public goods provision decreases the social welfare, due to the presence of adjustment costs in the objective function of the policy maker.

We see that the steady state provision of public goods increases with the time preference $r$ since $\frac{\partial \hat{a}}{\partial r} > 0$. The reason is that the more the home country is impatient the more it will be reluctant to postpone to invest in public infrastructures.

The impact of an increase of the productivity in providing public goods is however ambiguous. Indeed, according to (13) we have $\frac{\partial \hat{a}}{\partial \zeta} > 0$ if $\zeta < \overline{\zeta}$ ($\overline{\zeta} = \sqrt{\frac{\alpha (\delta - \xi)(r + \delta - \xi)}{\beta}}$) and $\frac{\partial \hat{a}}{\partial \zeta} < 0$ if $\zeta > \overline{\zeta}$. In other words, if productivity increases but remains at a low level ($\zeta < \overline{\zeta}$), the home country has an incentive to increase its attractiveness by augmenting public infrastructures. If the threshold $\overline{\zeta}$ is exceeded, then an increase in productivity induces too much public investment for a given level of taxes. Consequently, the home country increases its attractiveness to foreign investment by reducing its tax rate $\hat{T}$ and thus by reducing the provision of public goods.

Next we analyze the impact of a change in $\hat{a}$ originating, for example, from a shock affecting $\zeta$ or $r$ on the steady state size of the home economy. It is straightforward to show that $\frac{\partial \hat{S}}{\partial \hat{a}}$ has the opposite sign $\frac{\partial \hat{S}}{\partial \hat{a}}$ of $a^* - T^*$. Since condition $\hat{T} = \hat{a} - (a^* - T^*)$ must

$\text{According to (13) we could have chosen to express } \hat{T} \text{ (or } \hat{S} \text{) as an independent solution of the foreign decision instruments. In this case } \hat{a} \text{ and } \hat{S} \text{ (or } \hat{a} \text{ and } \hat{T} \text{) would depend on } a^* \text{ and } T^*.$

$\text{Since } \hat{T} = \hat{a} - (a^* - T^*), \text{ and thus } \frac{\partial \hat{T}}{\partial \hat{a}} \text{ and } \frac{\partial \hat{T}}{\partial a^*} \text{ are equal.}$

$\frac{\partial \hat{S}}{\partial \hat{a}} = -\frac{1}{\zeta (\hat{a} + T^* - a^*)} (a^* - T^*)$
hold in the steady state, both regions are equally attractive if the net amount of public goods offered by the small and large economies are either positive ($a^* > T^*$ and $\hat{a} > \hat{T}$). Conversely, both regions are equally unattractive if $T^* > a^*$ and $\hat{T} > \hat{a}$. The derivative $\frac{\partial \hat{S}}{\partial \hat{a}}$ is negative in the first case and positive in the second case. The impact of $\hat{a}$ on $\hat{S}$ can now be interpreted in the following way. If both regions are equally attractive, entrepreneurs have (for given moving costs) a preference for the country which levies lower taxes. If the small country increases the provision of public goods, it has also to increase its tax rate according to the above steady state condition. It follows that capital flows out of the small country and the size $\hat{S}$ shrinks consequently. If both regions are equally unattractive, entrepreneurs have (for given moving costs) a preference for the region which offers comparatively more public goods. Hence, an increase in $\hat{a}$ results in a capital inflow into the small economy and the size $\hat{S}$ expands consequently.

As it follows from the above proposition, if the trajectory of the small economy is not on its convergent path(s), it may go to one of the two possible corner steady states: the lower bound $\underline{S} = 0$ or the upper bound $\overline{S} = \frac{1}{2}$.

Let us first consider the case where the small economy could suffer from a possible economic collapse ($S(t) = 0$). In this case, the constraint on the state variable must be binding in order to exclude a negative population value and the steady state values of $\theta_1 = 0$ and $\theta_2$ has to be positive. Hence, the condition 12, in Proposition 1, should hold. Furthermore, once $S(t)$ has attained the lower bound it can no more decrease and it should be either constant or increasing, that is, $\dot{S}(t) \geq 0$, as it is shown in Proposition (1). In this case, we get

$$\underline{S} = 0, \quad \theta_1 = 0, \quad a = 0, \quad T = T^* - a^*, \quad \nu = 0, \quad \mu = \frac{\alpha_1}{r}(T^* - a^*), \quad \theta_2 = -\mu.$$  \hspace{1cm} (15)

Hence, the following result is straightforward.

**Proposition 3** For given parameters $\rho, \delta, \xi(< \delta), \zeta, k$, and for any policy variables set by the rest of the rest of the world $a^*$ and $T^*$, if $T^* < a^*$, the small state may heading towards an economic collapse ($\underline{S} = 0$)\(^{19}\) which is specified by (15). In this case, the multiplier $\theta_2$ is strictly

\(^{19}\)In proposition 2 we precise that this steady state is a saddle point.
It follows that a necessary condition for the appearance of the small state’s collapse is that the net benefit to investors is positive in the rest of the world \((a^* - T^* > 0)\). In that case, the small country is unable to tax \(^{20}a\) and therefore unable to offer public goods \((a = 0)\).

Let us now consider the case in which the home country could converge to the upper bound \(S(t) = \frac{1}{2}\). Note that the attainment of such a limit requires us to abandon the small country assumption which implies passivity of the rest of the world with regard to the home country’s policy choices. We however explore that case and show its possible economic relevance without modifying the small country assumption.

If \(S(t) = \frac{1}{2}\), the constraint on the state variable becomes binding and the steady state value of \(\theta_1\) has to be positive and \(\theta_2 = 0\). Hence, the condition 11, in Proposition 1, should hold. That states whenever \(S(t) = \frac{1}{2}\), population can not increase any more, and therefore, the change of population should be constant or decreasing: \(\dot{S}(t) \leq 0\). In the appendix, we show how the following steady state values are obtained

\[
\begin{align*}
\mathcal{S} &= \frac{1}{2}, \quad \bar{a} = \frac{\zeta (a^* - T^*)}{2(\xi - \delta) + \zeta}, \quad T = \bar{a} - (a^* - T^*). \\
\end{align*}
\]

Moreover, the costate variables become

\[
\begin{align*}
\nu &= \frac{1}{r + \delta - \xi - \frac{\zeta}{2}} \left( \frac{\alpha_1}{2} - \frac{\alpha_2 T}{4} - \beta \bar{a} \right), \\
\mu &= \frac{T}{r} \left( \alpha_1 - \frac{\alpha_2 T}{2} + \zeta \nu \right), \\
\widehat{\theta}_1 &= \left( 1 - \frac{2kr}{\rho T} \right) \mu > 0, \\
\widehat{\theta}_2 &= 0.
\end{align*}
\]

The above analysis lead to the following conclusion.

\(^{20}\)T = T^* - a^*
Proposition 4  For given parameters $\rho, \delta, \xi (< \delta), \zeta, k,$ and for any policy variables set by the rest of the world $a^*$ and $T^*$, if (a) $\xi < \delta < \xi + \frac{\zeta}{2}$ and $a^* > T^*$, or (b) $\delta > \xi + \frac{\zeta}{2}$ and $a^* < T^*$, the economy may converge to its upper-limit size, given by (16). In this case, the multiplier $\theta_1$ is given by (19) and is strictly positive with $\mu$ and $\nu$ given respectively by (18) and (17).

According to the above condition, it appears that the small economy can converge to its limit-size $S = \frac{1}{2}$ only if it offers the same net benefit to foreign investors as in the rest of the world ($\pi - T = a^* - T^*$). When $a^* - T^* > 0$ (case a)), the home country may converge to the upper bound value $S = \frac{1}{2}$ if its productivity in providing infrastructures, $\zeta$, is high enough ($\zeta > 2(\delta - \xi) > 0$). It follows that the home country’s size may move to $\frac{1}{2}$ by equating $\pi - T$ to $a^* - T^*$, without being hindered by the large economy.

If the net benefit to investors offered by the large economy is negative ($a^* - T^* < 0$)(case b)), the initially small country could end up in the situation in which it attracts all the world’s capital. This does however not occur if $\delta > \xi + \frac{\zeta}{2}$ (see case (b) of Proposition 4)\textsuperscript{21}. In other words, the home country’s size may converge to $S = \frac{1}{2}$, if $a^* - T^* < 0$ under the condition that the productivity factor $\zeta$ is bounded from above by $2(\delta - \xi) > 0$. It is however not realistic to assume that the large economy will remain passive and will not try to restore its attractiveness by reversing the sign of $a^* - T^*$. We therefore conclude that case (a) which has some economic relevance.

4  Conclusion

Many authors recognize that small countries dramatically lack (quantitatively and qualitatively) fundamental productive resources. These deficiencies appear especially in the form of limited productive capital, entrepreneurs and human capital. For simplicity, we merged these three types of production factors in one entity by assuming that capital owners, firm owners and workers are the same individuals bearing different mobility preferences.

\textsuperscript{21}If the depreciation rate and the user fee of public infrastructure are equal to zero ($\delta = \xi = 0$), the small country will never be able to attract all the world’s capital.
The particular situation we just featured contains a potential risk of collapse in the small economy. One way to escape this danger is to set up public policy strategies aimed at attracting foreign investments. These policies can be realized through different channels. The instruments which decision-makers are supposed to use in our paper, are tax instruments and the provision of public infrastructures enhancing private producers’ productivity. We focused on the strategic choices available to a small economy given the policy choices of the rest of the world. In other words, we did not model a game in which the large economy would react to the small country’s decisions. This assumption was justified by the fact that the home jurisdiction is supposed to be so small that it does induce any reaction from the large country. This assumption risks to become fragile if the initially small country is able to continually attract firms (and workers) from abroad. Such a possible occurrence lead us to be careful in the interpretation of the model’s steady states. More precisely, we had to exclude cases which otherwise would have contradicted the small country assumption. In a future work, however, our framework should be able to model a non cooperative game between the small and the both jurisdictions. Accordingly, it would be of a great interest to show how the new modelling would change the likely occurrence of the small country’s economic collapse.

Using an inter-temporal framework we characterize in our model the optimal strategic taxation path chosen by the policy makers in the small country. Applying dynamic optimization techniques, we derive a set of steady states and their stability conditions. One of three types of steady states may emerge. A first one in which the size of the initially small country attracts sufficiently external capital to grow as big as the foreign economy. A second equilibrium in which the small economy is no more economically viable because it looses all its productive capital. Finally, there may occur an intermediate situation in which the domestic economy survives while remaining small. In this scenario, there exists at least one intermediate steady state which exhibits saddle point stability. If the small economy does not undergo the optimal path leading to one of these intermediate equilibria it may converge to the worst case. The survival of a small economy is thus an important public policy issue which implies an appropriate choice.
of initial conditions and a dynamic update of the tax policy.

Appendix

Proof of Proposition 1

Define the current value of the Hamiltonian corresponding to the underlying economy

$$H(T, S, a, \mu, \nu) = \left[ \alpha_1 ST - \frac{\alpha_2}{2} (ST)^2 - \beta a^2 \right] - \mu \rho \left( b^*(t) - a(t) - \frac{T(t)}{k} \right) + \nu \left[ (\xi - \delta) a(t) + \zeta ST \right]$$

and the following Lagrangian which accounts for the state constraints\(^ {22}\) of the model

$$L(T, S, a, \mu, \nu, \theta_1, \theta_2) = H(T, S, a, \mu, \nu) + \theta_1 \rho \left( b^*(t) - \frac{a(t) - T(t)}{k} \right) - \theta_2 \rho \left( b^*(t) - \frac{a(t) - T(t)}{k} \right).$$

It is easy to see that \(H(T, S, a, \mu, \nu)\) is concave with respect to the state variables \(S\) and \(a\). Hence the first order conditions are necessary and sufficient for the existence of an optimum. Deriving the first order conditions from the Hamiltonian we obtain (8) with respect to \(T\), while we get (9) and (10) with respect to both state variables. The multipliers of the state boundary constraints check (11) and (12). That finishes the proof.

Proof of Proposition 2

We first state the existence of possible interior steady state(s) in addition to that given in Proposition 2. Then we give the proof.

**Proposition 5** The following additional steady state(s) may appear.

\(^{22}\)See, for example, Chiang, page 301-302.
(II.1) If \( a^* - T^* = -\frac{kr(\delta - \xi)}{4\zeta\rho} < 0 \), there is a further interior steady state specified by

\[
\hat{T}_1 = \frac{kr(\delta - \xi)}{2\zeta\rho}, \quad \hat{a}_1 = (a^* - T^*) + \hat{T}_1, \quad \hat{S}_1 = \frac{\rho\hat{T}_1}{kr}
\]  

(21)

and two costate variables \(^{23}\)

\[
\hat{\nu}_1 = \frac{\alpha_2 \hat{S}_1^2 \hat{T}_1 + \beta \hat{a}_1 - \alpha_1 \hat{S}_1}{\zeta \hat{S}_1 - r - \delta + \xi}, \quad \hat{\mu}_1 = \frac{k [(r + \delta - \xi) \hat{\nu}_1 + \beta \hat{a}_1]}{\rho}.
\]  

(22)

(II.2) If \( a^* - T^* = 0 \), the additional steady state is

\[
\hat{\nu}_2 = \frac{kr(\delta - \xi)}{\zeta\rho}
\]  

(23)

and we obtain the remaining steady state variables by replacing the subscript 1 by 2 in (21) and (22).

(II.3) If \( a^* - T^* > 0 \), the second steady state is specified by

\[
\hat{T}_3 = \frac{kr}{2\zeta\rho} \left[ (\delta - \xi) + \sqrt{(\delta - \xi)^2 + \frac{4\zeta\rho}{kr}(\delta - \xi)(a^* - T^*)} \right]
\]  

(24)

and the others are the same as in (21) and (22) by replacing the subscript 1 to 3.

(II.4) If \( -\frac{kr(\delta - \xi)}{4\zeta\rho} < a^* - T^* < 0 \), there are another two interior steady states where

\[
\hat{T}_{4,5} = \frac{kr}{2\zeta\rho} \left[ (\delta - \xi) \pm \sqrt{(\delta - \xi)^2 + \frac{4\zeta\rho}{kr}(\delta - \xi)(a^* - T^*)} \right]
\]  

(25)

and the remaining the others are the same as in (21) and (22) by replacing the subscript 1 by 4 and 5.

Proof.

\(^{23}\)The condition \( \zeta \hat{S}_1 - r - \delta + \xi \neq 0 \) must hold.
At the interior steady state, \( \theta_1 = 0, \theta_2 = 0 \) and we can rewrite the first order condition as follows

\[
\begin{align*}
T &= \frac{\alpha_1 S - \frac{\rho \mu}{k} + \zeta S \nu}{\alpha_2 S^2} \\
\dot{S} &= -\rho (b^* - \frac{a - T}{k}), \\
\dot{a} &= (\xi - \delta)a + \zeta S T, \\
\dot{\mu} &= r \mu - \rho T \mu - (\alpha_1 - \alpha_2 S T) T, \\
\dot{\nu} &= (r + \delta - \xi) \nu + \beta a - \frac{\xi}{\zeta} \mu.
\end{align*}
\]

(26)

We rewrite the first equation as follows

\[
\frac{\rho \mu}{k S} = \alpha_1 + \zeta \nu - \alpha S T.
\]

(27)

Substituting (27) into the 3rd equation and arranging leads to the

\[
\dot{\mu} = r \mu - \frac{\rho T \mu}{k S}.
\]

Hence, \( \dot{\mu} = 0 \) leads to two cases: \( \hat{\mu} = 0 \) or \( r = \frac{\rho T}{k S} \).

We consequently have two groups of steady states.

(I) \( \hat{\mu} = 0 \).
It is easy to check that the interior steady states are given by (13) and (14). To determine their stability, we consider the corresponding Jacobian

$$
J_f = \begin{pmatrix}
\frac{\rho \alpha_1 + \zeta \hat{\nu}}{k \alpha_2} & \frac{\rho^2}{\alpha_2 k^2 S^2} & -\frac{\rho \zeta}{\alpha_2 k S} \\
0 & \xi - \delta & -\frac{\zeta \rho}{\alpha_2 k S} \\
0 & 0 & -\frac{\rho \alpha_1 + \zeta \hat{\nu}}{k \alpha_2} + r \\
0 & \beta & -\frac{\rho}{k} & r + \delta - \xi
\end{pmatrix}
$$

It is easy to show that the eigenvalues of the Jacobian are given by

$$
e_1 = \frac{\hat{\rho} T}{k S} > 0, \quad e_2 = r - \frac{\hat{\rho} T}{k S} > 0 \ (\text{or} \ < 0),
$$

$$
e_{3,4} = \frac{r}{2} \pm \frac{1}{2} \sqrt{r^2 + 4 \left[ \frac{\beta \zeta^2}{\alpha_2} + (r + \delta - \xi)(\delta - \xi) \right]}.
$$

Hence, $e_3 > 0$ and $e_4 < 0$, which guarantees one dimensional convergence to the steady state. The other part of the convergence depends on $e_2$ is negative or not, that is, the relation of $r$ with respect to the other parameters and exogenous variables.

(II) $r = \frac{\hat{\rho} T}{k S}$

In this case, we have $S = \frac{\hat{\rho} T}{k r}$. $\dot{S} = 0$ leads to $a = (a^* - T^*) + T$ and $\dot{a} = 0$ gives $\zeta ST = (\delta - \xi)a$. Combining these conditions, we obtain

$$
\frac{\zeta \rho}{k r} T^2 - (\delta - \xi)T - (\delta - \xi)(a^* - T^*) = 0,
$$
which yields to two roots

\[
T = \frac{kr}{2\zeta \rho} \left[ (\delta - \xi) \pm \sqrt{(\delta - \xi)^2 + \frac{4\zeta \rho}{kr}(\delta - \xi)(a^* - T^*)} \right]
\]

and if \( \Lambda = (\delta - \xi)^2 + \frac{4\zeta \rho}{kr}(\delta - \xi)(a^* - T^*) > 0 \), both roots are real. Furthermore, depending on \( \Lambda \) is larger or smaller than \((\delta - \xi)^2\), we have different conditions which leads to positive \( T \)'s and which serve as the other steady states. \( \square \)

**Proof of Proposition 4**

In the upper-corner solution case, \( S = \frac{1}{2} \) and hence, \( \theta_2 = 0 \) and \( \theta_1 > 0 \). According to the complementary slackness conditions, we must have \( \bar{a} - \bar{T} = a^* - T^* \), that is, \( \bar{T} = \bar{a} - (a^* - T^*) \).

From \( \dot{a} = 0 \), we obtain

\[
\bar{a} = \frac{\xi (a^* - T^*)}{\xi + \frac{\xi}{2} - \delta}.
\]  (28)

The solution \( \bar{a} \) is be positive if and only if \( \delta > \xi + \frac{\xi}{2} \) and \( a^* < T^* \), or \( (\xi < \delta < \xi + \frac{\xi}{2} \) and \( a^* > T^* \).

The condition \( \dot{\mu} = 0 \) leads to

\[
\frac{v}{2} \mu = \frac{T}{2k} (\mu - \bar{\theta}_1)
\]  (29)

or

\[
\bar{\theta}_1 = \left( \frac{2kr}{\rho T} - 1 \right) \mu.
\]  (30)

Similarly, \( \dot{\nu} = 0 \) leads to

\[
(r + \delta - \xi)\nu = \frac{\rho}{k} (\mu - \bar{\theta}_1) - \beta \bar{a}.
\]  (31)

On the other hand, (8) can be rewritten as

\[
\alpha_2 \bar{S} \bar{T} = \alpha_1 - \frac{\rho \mu}{k} \bar{\theta}_1 + \zeta \nu
\]  (32)
which gives

\[-\frac{\rho}{k}(\bar{\mu} - \bar{\theta}_1) = \frac{\alpha_2 T}{4} - \frac{\alpha_1}{2} - \frac{\zeta \nu}{2} .\]

Combining with (31), it follows

\[\nu = \frac{1}{r + \delta - \zeta - \frac{\zeta}{2} \left[ \frac{\alpha_1}{2} - \beta \bar{\mu} - \frac{\alpha_2 T}{4} \right]} \tag{33}\]

and

\[\bar{\mu} = \frac{T}{r} \left( \alpha_1 + \zeta \nu - \frac{\alpha_2 T}{2} \right) . \tag{34}\]

Hence, we obtain a complete solution for the steady state \( \bar{S} = \frac{1}{2} \). The above solutions are meaningful if and only if \( \bar{\theta}_1 > 0 . \)
